The Statistical model $\mathcal{F}_{4,2}$

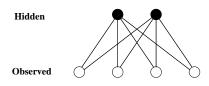

Figure: The undirected graphical model $\mathcal{F}_{4,2}$.

The set of all possible joint probability distributions (X_1, X_2, X_3, X_4) forms an algebraic variety $\mathcal M$ inside Δ_{15} with expected codimension one and (multi)homogeneous defining equation f.

Problem (Drton-Sturmfels-Sullivant)

Find the degree and the defining polynomial f / Newton polytope of \mathcal{M} .

Geometry of the model $\mathcal{F}_{4,2}$

Parameterization of the model: $p \colon \mathbb{R}^{32} \to \mathbb{R}^{16}$,

$$p_{ijkl} = \sum_{s=0}^{1} \sum_{r=0}^{1} a_{si} b_{sj} c_{sk} d_{sl} e_{ri} f_{rj} g_{rk} h_{rl} \text{ for all } (i, j, k, l) \in \{0, 1\}^4.$$

Using homogeneity and the distributive law

$$p: (\mathbb{P}^1 \times \mathbb{P}^1)^8 \to \mathbb{P}^{15} \quad p_{ijkl} = (\sum_{s=0}^1 a_{si} b_{sj} c_{sk} d_{sl}) \cdot (\sum_{r=0}^1 e_{ri} f_{rj} g_{rk} h_{rl}).$$

So we have a coordinatewise product of two parameterizations of $\mathcal{F}_{4,1}$: the graphical model corresponding to the 4-claw tree with binary nodes.

NICE FACTS: We know a lot about $\mathcal{F}_{4,1}$ and coordinatewise products of projective varieties...

Geometry of the model $\mathcal{F}_{4,2}$

Fact

- **1** The binary 4-claw tree model is $Sec^1(\mathbb{P}^1 \times \mathbb{P}^1 \times \mathbb{P}^1 \times \mathbb{P}^1) \subset \mathbb{P}^{15}$.
- Coordinatewise products of parameterizations corresponds to Hadamard products of algebraic varieties

Definition

 $X,Y\subset\mathbb{P}^n$, the **Hadamard product** of X and Y is

$$X \cdot Y = \overline{\{x \cdot y := (x_0 y_0 : \dots : x_n y_n) \mid x \in X, y \in Y, x \cdot y \neq 0\}} \subset \mathbb{P}^n,$$

Geometry of the model $\mathcal{F}_{4,2}$

Corollary

The algebraic variety of the model is $\mathcal{M}=X$ where X is the first secant variety of the Segre embedding $\mathbb{P}^1\times\mathbb{P}^1\times\mathbb{P}^1\times\mathbb{P}^1\hookrightarrow\mathbb{P}^{15}$.

Remark

The model is highly symmetric. It is invariant under relabeling of the four observed nodes and changing the role of the two states (0 and 1). Therefore, we have an action of the group $B_4 = \mathbb{S}_4 \ltimes (\mathbb{S}_2)^4$, the group of symmetries of the 4-cube.

Useful facts about X:

- The ideal I(X) is a well-studied object: it is the 9-dim *irreducible* projective variety of all $2 \times 2 \times 2 \times 2$ -tensors of tensor rank ≤ 2 .
- 2 Known set of generators for I(X): 3×3 -minors of all three 4×4 -flattenings of these tensors \leadsto 48 polynomials.

Tropicalizing the model

Definition

For an algebraic variety $X\subset \mathbb{C}^n$ with defining ideal $I=I(X)\subset \mathbb{C}[x_1,\ldots,x_n]$, the tropicalization of X or I is defined as:

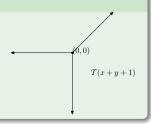

$$\mathcal{T}X = \mathcal{T}I = \{ w \in \mathbb{R}^n \, | \, \text{in}_w(I) \text{ contains no monomial} \}$$

where $\mathrm{in}_w(I) = \langle \mathrm{in}_w(f) : f \in I \rangle$, and $\mathrm{in}_w(f)$ is the sum of all *nonzero* terms of $f = \sum_{\alpha} c_{\alpha} x^{\alpha}$ such that $\alpha \cdot w$ is **maximum**.

Example

$$L = (x + y + 1 = 0) \subset \mathbb{C}^2$$

gives the well-known picture:

Remark

Basic features of $\mathcal{T}X$ for $X \subset \mathbb{P}^n$ with homogeneous ideal I = I(X):

- 1 It is a rational polyhedral subfan of the Gröbner fan of I.
- ② If I is prime, then TX is pure of the same dimension as X (Bieri-Groves Thm) and it is connected in codimension one.
- **3** Maximal cones have canonical multiplicities attached to them. With these multiplicities, TX satisfies the balancing condition.
- If X is a hypersurface, TX is the collection of all codimension one cones in the normal fan of the Newton polytope of X. The multiplicity of a maximal cone is the lattice length of the corresponding edge in the polytope.
- **5** The lineality space of the fan TX is the set

$$L = \{ w \in \mathcal{T}X : in_w(I) = I \}.$$

- It describes the action of a maximal torus on X (diagonal action by the lattice $L \cap \mathbb{Z}^{n+1}$).
- Morphisms can be tropicalized and monomial maps have very nice tropicalizations.

Theorem (Sturmfels-Tevelev)

Let $A \in \mathbb{Z}^{d \times n}$, defining a monomial map $\alpha \colon (\mathbb{C}^*)^n \to (\mathbb{C}^*)^d$ and a canonical linear map $A \colon \mathbb{R}^n \to \mathbb{R}^d$. Let $V \subset (\mathbb{C}^*)^n$ be a subvariety. Then $\mathcal{T}(\alpha(V)) = A(\mathcal{T}V).$

Moreover, if α induces a generically finite morphism on V, we have an explicit formula to push forward the multiplicities of $\mathcal{T}V$ to multiplicities of $\mathcal{T}(\alpha V)$.

Here, $\mathcal{M} = X \cdot X = \alpha(X \times X)$, and A is the matrix $(Id_{16} \mid Id_{16})$.

Theorem (— -Tobis-Yu, Allermann-Rau, ...)

Let $X,Y\subset\mathbb{C}^m$ be two irreducible varieties. Then

$$\mathcal{T}(X \times Y) = \mathcal{T}X \times \mathcal{T}Y$$

as weighted polyhedral complexes, with $m_{\sigma imes au} = m_{\sigma} m_{ au}$ for maximal cones.

Corollary: $TM = T(X \cdot X) = TX + TX$ (as sets!).

Computing TM from TX

 $\mathcal{T}X$ can be computed with Gfan. In particular,

- 10-dim. simplicial fan in \mathbb{R}^{16} ,
- 5-dim. lineality space,
- f-vector= (381, 3436, 11236, 15640, 7680),
- 13 rays and 49 maximal cones up to B_4 -symmetry.

Thus we know TM = TX + TX as a set!

- Dimension = 15 in \mathbb{C}^{16} , so \mathcal{M} is a hypersurface!
- Number of maximal cones in TX + TX = 6865824.
- $18\,972$ maximal cones up to B_4 -symmetry.

BUT we want more...

We want to compute multiplicities at regular points of TM.

Our map α is monomial BUT NOT generically finite. However, it is very close to being generically finite. We generalize the [ST] formula to obtain multiplicities in \mathcal{TM} .

Main results

$$(\mathbb{C}^*)^n \supseteq V \xrightarrow{\alpha} W \subseteq (\mathbb{C}^*)^d$$

$$\pi \downarrow \qquad \qquad \downarrow \pi \qquad \qquad \text{where } H = \Lambda \otimes_{\mathbb{Z}} \mathbb{C}^* \sim (\mathbb{C}^*)^{\dim \Lambda}.$$

$$V' = V/H \xrightarrow{\bar{\alpha}} W/\alpha(H),$$

Theorem (— -Tobis-Yu)

Let $V \subset (\mathbb{C}^*)^n$ be a subvariety with torus action given by a lattice Λ and take the quotient by this action V' = V/H.

Assume that $\Lambda' = A(\Lambda)$ is a primitive sublattice of \mathbb{Z}^d and that $\bar{\alpha}$ is generically finite on V' of degree δ . Then:

$$m_w = \frac{1}{\delta} \sum_{\substack{\pi(v) \\ A : v = w}} m_v \cdot index(\mathbb{L}_w \cap \mathbb{Z}^d : A(\mathbb{L}_v \cap \mathbb{Z}^n)).$$

We assume that the number of such $\pi(v)$ is finite, all of them are regular in TV, and \mathbb{L}_v , \mathbb{L}_w are local linear spans of $v \in TV$ and $w \in A(TV)$.

The Newton polytope of the implicit equation

KEY: We can recover the *Newton polytope of* f from $\mathcal{T}(f)$ given as a collection of cones *with multiplicities*.

- **1** $\mathcal{T}(f)$ is the union of the codim 1 cones of the *normal fan of* NP(f).
- $oldsymbol{\circ}$ the multiplicity of a maximal cone is the lattice length of the edge of $\mathrm{NP}(f)$ normal to that cone.

Theorem (Dickenstein-Feichtner-Sturmfels)

Suppose $w \in \mathbb{R}^n$ is a generic vector so that the ray $(w - \mathbb{R}_{>0} e_i)$ intersects $\mathcal{T}(f)$ only at regular points of $\mathcal{T}(f)$, for all i. Let \mathcal{P}^w be the vertex of the polytope $\mathcal{P} = NP(f)$ that attains the maximum of $\{w \cdot x : x \in NP(f)\}$. Then the i^{th} coordinate of \mathcal{P}^w equals

$$\mathcal{P}_i^w = \sum_v m_v \cdot |l_{v,i}|,$$

where the sum is taken over all points $v \in \mathcal{T}(f) \cap (w - \mathbb{R}_{>0}e_i)$, m_v is the multiplicity of v in $\mathcal{T}(f)$, and $l_{v,i}$ is the i^{th} coordinate of the primitive integral normal vector to $\mathcal{T}(f)$ at v.

The Newton polytope of the implicit equation

Theorem (— -Tobis-Yu)

The hypersurface ${\cal M}$ has multidegree (110,55,55,55,55) with respect to the grading defined by the matrix

Question: Is there hope of computing NP(f) by iterating Ray-shooting? Bottleneck: Going through the list of all maximal cones supporting \mathcal{TM} ($\sim 7\,000\,000$).

We can do better! → Shoot rays and walk from chamber to chamber.

Theorem (— -Tobis-Yu)

The Newton polytope of f has $17\,214\,912$ vertices in $44\,938$ orbits and $70\,646$ facets in 246 orbits under the symmetry group B_4 .

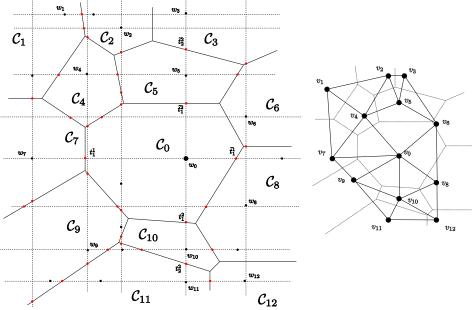

Figure: Ray-shooting and walking algorithms combined. Starting from chamber C_0 we shoot and walk from chamber to chamber, and from vertex to vertex in NP(f).

Certifying the Newton polytope of the implicit equation

Given ${\mathcal S}$ a (partial) list of vertices of ${\rm NP}(f)$, we construct

$$Q = conv \, hull(S).$$

FACT: $Q = NP(f) \iff$ all facets of Q are facets of NP(f).

Lemma

Let $w \in \mathbb{R}^n$ and $\mathcal{T}(f)$ be a tropical hypersurface given by a collection of cones, but with no prescribed fan structure. Let d be the dimension of its lineality space. Let $\mathcal{H} = \{\sigma_1, \dots, \sigma_l\}$ be the list of cones containing w. Let q_i be the normal vector to the cone σ_i for $i=1,\dots,l$. TFAE:

- w is a ray of $\mathcal{T}(f)$,
- $\dim_{\mathbb{R}} \mathbb{R}\langle q_1, \dots, q_l \rangle = n d 1$,
- w is a facet direction of NP(f).

Completing the polytope

Definition

 $\mathcal{P} \subset \mathbb{R}^N$ full dim'l and v vertex of \mathcal{P} . The tangent cone of \mathcal{P} at v is:

$$\mathcal{T}_v^{\mathcal{P}} := v + \mathbb{R}_{\geq 0} \langle w - v : w \in \mathcal{P} \rangle = v + \mathbb{R}_{\geq 0} \langle e : e \text{ edge of } \mathcal{P} \text{ adjacent to } v \rangle.$$

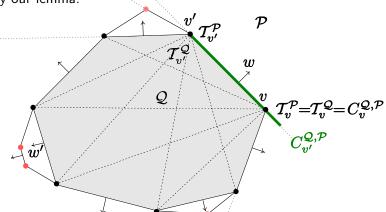

Remark

- $\mathcal{T}_v^{\mathcal{P}}$ is a polyhedron with only ONE vertex v.
- $\mathcal{P} = \bigcap_{v \text{ vertex of } \mathcal{P}} \mathcal{T}_v^{\mathcal{P}}$.
- Facet directions of $\mathcal P$ are facet directions in $\mathcal T_v^{\mathcal P}$ for some vertex v.
- $T_v^{\mathcal{Q}} \subseteq T_v^{\mathcal{P}}$ and if $T_v^{\mathcal{Q}} = T_v^{\mathcal{P}}$ then the extremal rays of $T_v^{\mathcal{Q}}$ are edge directions of \mathcal{P} . We have these edge directions from T(f) (~ 15788).

Definition

$$C_v^{\mathcal{Q},\mathcal{P}} := v + \mathbb{R}_{\geq 0} \langle w - v : w \text{ vertex of } \mathcal{Q}, w - v \sim \text{edge of } \mathcal{P} \rangle \subset \mathcal{T}_v^{\mathcal{Q}}.$$

- In practice: number of generating rays in $C_v^{\mathcal{Q},\mathcal{P}}$ is about 30 (vs. 17 million rays for $\mathcal{T}_v^{\mathcal{Q}}$!).
- ullet Can test $C_v^{\mathcal{Q},\mathcal{P}}\supset\mathcal{T}_v^{\mathcal{Q}}$ by computing facets of $C_v^{\mathcal{Q},\mathcal{P}}$ with Polymake.
- If $C_v^{\mathcal{Q},\mathcal{P}} = \mathcal{T}_v^{\mathcal{Q}}$ can test if facet directions are facet directions of $\mathcal{T}_v^{\mathcal{P}}$ by our lemma.

• Last: certify that the facet with direction w in $\mathcal{T}_v^{\mathcal{Q}}$ is supported on v. We can do this by using ray-shooting with perturbed w.
