

LECTURE 30

30.1

I. The Covariant Differential

In MTW read section 14.5

II. The Covariant Derivative

In MTW read Sections 8.3, 8.5, 10.3, 10.4
Box 10.2, 10.3

I. The Covariant Differential

The parallel-transport-given isomorphism between adjacent tangent spaces is condensed into the vectorial differentials

$$de_i = e_j \otimes \omega^j_i \quad (30.1)$$

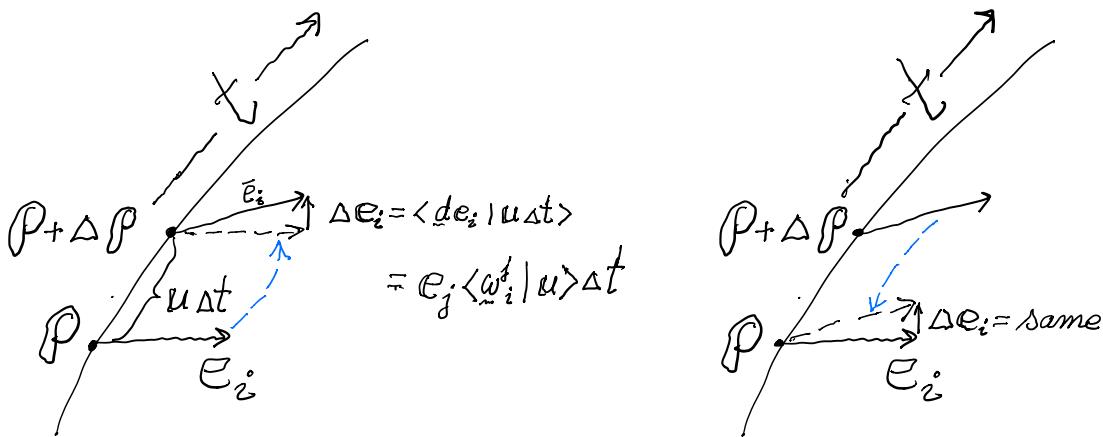

Figure 30.1: Along a t -parametrized curve a preexisting t -parametrized family of basis vectors deviates from being parallel.

Relative to the coordinate cotangent basis $\{dx^i\}$ the connection one-forms

$$\omega^j_i = \Gamma^j_{ik} dx^k$$

are given in terms of the functions

$$\Gamma^i_{jk}(P) = \Gamma^i_{jk}(x^1, \dots, x^n),$$

the Christoffel symbols of the 2nd kind. The law of parallel transport of vectors and tensors is mathematized by these functions.

Given a smooth vector field

$$v = v^i(x^1, \dots, x^n) e_i,$$

how does one extend this law to such a vector field?

The means of parallel transporting a vector is to apply the product rule governing a differential. A differential is based on taking differences, in this case between a pre-existing vector at a point and the parallel translate from any one of its neighbors as depicted in Figure 30.2,

$$\Delta V = V_{P+\Delta P} - (\text{parallel transport of } V \text{ from } T_P(M) \text{ to } T_{P+\Delta P}(M))$$

$$= V_P - (\text{parallel transport of } V \text{ from } T_{P+\Delta P}(M) \text{ to } T_P(M))$$

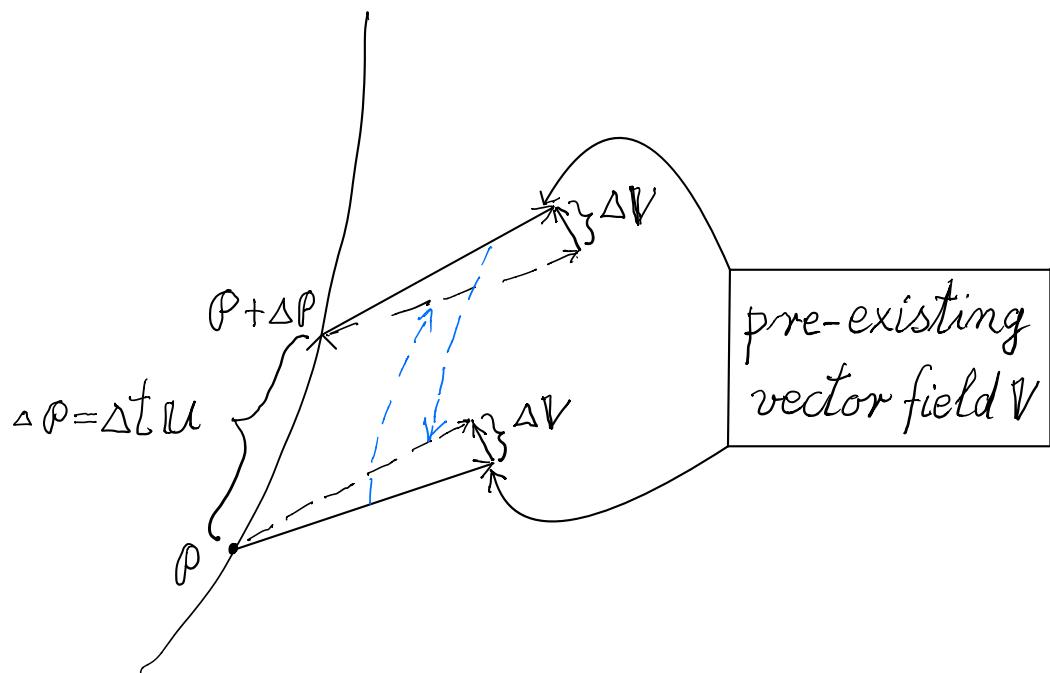

Figure 30.2: A pre-existing non-parallel vector field v deviates (by Δv) from parallelism (stippled blue arrows) among vectors at nearby points P and $P + \Delta P$.

This difference is well-defined because it is of two vectors at the same point.

In addition, the dominant part of its difference depends only linearly on the displacement vector $\Delta \mathbf{P} = \Delta t \mathbf{u}$ separating $\mathbf{P} + \Delta \mathbf{P}$ from \mathbf{P} . Ignoring higher order dependencies one has at point \mathbf{P}

$$\Delta v_p(\Delta t \mathbf{u}) = \Delta (\mathbf{e}_i v^i) = \mathbf{e}_i \Delta v^i + \Delta \mathbf{e}_i v^i \quad (30.2)$$

Recall that

(i) the deviation of \mathbf{e}_i from parallelism is

$$\begin{aligned} \Delta \mathbf{e}_i &= \langle \mathbf{e}_j \cdot \underline{\omega}_i^j | \mathbf{u} \rangle t \\ &\equiv \langle d\mathbf{e}_i | \mathbf{u} \rangle t \end{aligned}$$

and that

(ii) the Taylor series of v^i , namely, $v^i(\underbrace{\mathbf{C}(\Delta t)}_{\mathbf{P} + \Delta t \mathbf{u}_p}) = v^i(\underbrace{\mathbf{C}(0)}_{\mathbf{P}}) + \Delta t \mathbf{u}(\underline{v^i}) \Big|_{\mathbf{P}} + \frac{(\Delta t)^2}{2!} \mathbf{u} \mathbf{u} v^i \Big|_{\mathbf{P} = \mathbf{C}(0)} + \dots$

gives us

$$\begin{aligned} \Delta v^i &= v^i(\mathbf{P} + \Delta t \mathbf{u}_p) - v^i(\mathbf{P}) \\ &= \Delta t \mathbf{u}_p(v^i) + \frac{\Delta t^2}{2} \mathbf{u}_p \mathbf{u}_p(v^i) + \dots \quad (\text{Lecture 26, page 26.8}) \\ &= \Delta t \langle dv^i | \mathbf{u} \rangle + \dots \quad (\text{Lecture 25, page 25.5}) \end{aligned}$$

Applying these facts to the deviation Δv , Eq.(30.2) on page 30.4, one finds that the dominant linear contribution to Δv is

$$\Delta v = \mathbf{e}_j \langle dv^i | \mathbf{u} \rangle \Delta t + \langle d\mathbf{e}_i | \mathbf{u} \rangle v^i \Delta t$$

Condense these observations and calculations (namely (i) and (ii)) into the following

Definition ("Covariant differential of a vector")

30,5

on page 30.2

In moving from P to $P + \Delta P$, let Δv as given by Eq. (30.1) be the principal linear part of the deviation of the vector field $v = e_i v^i$ from parallelism.

~~vector-valued~~
Then the linear map

$$dv: T_p(M) \longrightarrow T_p(M)$$

$$u \wedge t \rightsquigarrow \langle dv | u \wedge t \rangle = \langle e_i dv^i + de_i v^i | u \wedge t \rangle \equiv \Delta v$$

is called the covariant differential of v . This differential is a vector valued 1-form, which in light of Eq. (30.1) on page 30.2 is

$$dv = e_i \otimes (dv^i + \omega_j^i v^j) = e_i (dv^i + \omega_j^i v^j). \quad (30.3)$$

It is a tensor of rank (1).

Comment 1.

This definition is general; it applies regardless of one's choice of basis.

Relative to a coordinate-induced basis and its dual,

$$\{e_i = \frac{\partial}{\partial x^i}\} \text{ and } \{dx^k\},$$

the covariant differential of $v = v^i e_i$ is

$$dv = e_i \left(\frac{\partial v^i}{\partial x^k} dx^k + \Gamma_{jk}^i dx^k \cdot v^j \right)$$

$$dv = e_i \left(\underbrace{\frac{\partial v^i}{\partial x^k} + \Gamma_{jk}^i v^j}_{v^i_{;k}} \right) dx^k \quad (30.4)$$

$$v^i_{;k}$$

The components $v^i_{;k}$ are those of a tensor of rank (1), and

they are called the components of the covariant derivative of v .

Comment 2

The derivative

$$\lim_{\Delta t \rightarrow 0} \frac{\Delta v}{\Delta t} = \langle \frac{dv}{dt} u \rangle \quad (30.4)$$

is v 's rate of deviation from parallelism during motion into the direction u .

This process is concretized by an airplane flying along a great circle from New York to London. The interior of the airplane has its three basis vectors bolted to the aircraft.

They point forward-backward, up-down, and left-right. The aircraft carries a compass and its needle always points to the North. As the aircraft flies with non-zero velocity along its path the compass needle will rotate with non-zero angular velocity relative to the aircraft's basis vectors. This is because these vectors deviate from being parallel to the North Star direction. They rotate relative to the direction of the compass needle. The law governing this rotation is given by Eq. (30.4).

Comment 3.

By not specifying, but nevertheless implying, the direction

of motion in Eq.(30.4), $\frac{dV}{dt} = \langle dV|u \rangle$, one is led to the concept of

dV as "the rate of deviation from parallelism due to motion into an as-yet-unspecified direction.

Comment 4.

In one's motion along the direction u , the vector $v = e_j v^j$ suffers from two causes in its rate of change as expressed by

$$\langle dV|u \rangle = e_j \left(\frac{\partial v^j}{\partial x^k} + \Gamma_{ik}^j v^i \right) u^k$$

(i) The components v^j change, which is mathematized by the directional derivative,

$$D_u v^j = \frac{\partial v^j}{\partial x^k} u^k$$

(ii) The basis vectors get altered (rotated, expanded, etc).

This results in an additional change, one in the form of the transformation

$$[\Gamma_{ik}^j u^k] v^i.$$

II. The Covariant Derivative

The covariant differential dV , Eqs. (30.3)-(30.4), of the vector field v is the portal to extending the concept of the directional derivative of a scalar field to that of a vector field.

A) Let f be a scalar field. Recall (Lecture 23) that the differential df

(i) is defined by $\langle df|u \rangle = u(f)$

(ii) is linear: $\langle df|u_1 + u_2 \rangle = \langle df|u_1 \rangle + \langle df|u_2 \rangle$

$$\langle df|gu \rangle = g \langle df|u \rangle \quad g \in C(M, \mathbb{R})$$

(iii) satisfies the product rule: $\langle d(fg)|u \rangle = \langle df|u \rangle g + f \langle dg|u \rangle \quad g \in C^\infty(M, \mathbb{R})$

B) Let $v = e_i v^i$ be a vector field. Recall from Page 30.5 that the differential dV

(i) is defined by $\langle dV|u \rangle = \langle e_j \otimes d v^j + e_j \otimes \omega^j_i v^i | u \rangle$

(ii) is linear: $\langle dV|u_1 + u_2 \rangle = \langle dV|u_1 \rangle + \langle dV|u_2 \rangle$

$$\langle dV|gu \rangle = g \langle dV|u \rangle \quad g \in C^\infty(M, \mathbb{R})$$

(iii) satisfies the product rule: $\langle d(fv)|u \rangle = f \langle dV|u \rangle + \langle df|u \rangle v$

C) Both df and dV share the linearity and the product rule property when these scalar/vectorial one-forms are evaluated on any $u \in T_p(M)$. This commonality implies the definition of a (directional) derivative operator whose domain includes both scalar and vector field. This is achieved by the following definition and thereby condenses the essentials of Parallel transport theory into 4 statements

Definition (" $\nabla_u V$ ")

$$(1) \quad \nabla_{u_1}(V_1 + V_2) = \nabla_{u_1}V_1 + \nabla_{u_1}V_2$$

"distributivity"

$$(2) \quad \nabla_{u_1+u_2}V = \nabla_{u_1}V + \nabla_{u_2}V$$

"distributivity"

(3) For any scalar field f

$$\nabla_{fu} V = f \nabla_u V$$

$$(4) \nabla_u(fV) = \nabla_u(f)V + f \nabla_u V$$

"pointwise linearity"

"product ("Leibnitz") rule"

These four equations are to be compared and contrasted with the corresponding directional derivatives $\nabla_u g$ of the scalar field g :

$$(1) \nabla_u(g_1 + g_2) = \nabla_u g_1 + \nabla_u g_2$$

$$(2) \nabla_{u_1+u_2} g = \nabla_{u_1} g + \nabla_{u_2} g$$

(3) For any scalar field f

$$\nabla_{fu} g = f \nabla_u g$$

$$(4) \nabla_u(fg) = \nabla_u(f)g + f \nabla_u g$$

Comment

1. The operator ∇ is called the covariant derivative operator.

2. The operator d is called the covariant differential operator.

3. " $\nabla = d$ "
↑ Cartan before WW II.

Post WW II.
