Project 2

Instructions: This project is worth a total of 10 points. You may use any notes or books that you wish but you must work individually. The only computation aid which you may use is MATLAB, unless otherwise indicated. The primary reference for this project are the notes on Markov processes which can be found at: http://www.math.ohio-state.edu/~husen/teaching/571/markov_1.pdf. Make sure to write clearly and justify your answers.

(1.) (5 pts.) Suppose that one type of atom can be in one of three quantum states which are denoted $Q_1$, $Q_2$ and $Q_3$. Given a collection of these atoms, it is found that each measurement perturbs the atoms and each atom has a chance of switching its quantum state. The probabilities that they do are given by:

- $Q_1 \rightarrow Q_2; P = 0.27$
- $Q_1 \rightarrow Q_3; P = 0.34$
- $Q_2 \rightarrow Q_1; P = 0.63$
- $Q_2 \rightarrow Q_3; P = 0.12$
- $Q_3 \rightarrow Q_1; P = 0.44$
- $Q_3 \rightarrow Q_2; P = 0.25$

(a.) Find the transition matrix $M$ of this Markov process.

(b.) Suppose that initially there are 95 atoms in state $Q_1$, 81 in state $Q_2$ and 62 in state $Q_3$. What is the resulting distribution after 5 measurements?

(c.) Find the steady-state probability vector $x_s$ of this process.

(2.) (5 pts.) Suppose that one type of atom can exist in a ground state $G$ or be in one of 4 excited states $E_1$, $E_2$, $E_3$ and $E_4$. Suppose that a collection of these atoms is irradiated by a photon pulse. If an atom is in the ground state, then it has a probability of 0.37 of being excited to state $E_1$, a probability of 0.13 of being excited to state $E_2$ and it never transitions to $E_3$ or $E_4$. If it is in state $E_1$ it has a probability of 0.65 of dropping to the ground state, a probability of 0.13 of being excited to state $E_2$ a probability of 0.02 of being excited to state $E_3$ and a probability of 0.02 of being excited to state $E_4$. If it is in state $E_2$ it has a probability of 0.87 of dropping to the ground state, a probability of 0.03 that it transitions to state $E_1$ and it never transitions to $E_3$ or $E_4$. If it is in state $E_3$ or $E_4$ it has a 0.93 probability of dropping to state $E_2$ and a 0.07 probability of remaining in its current state.

(a.) Find the transition matrix $M$ of this Markov process.

(b.) Find the steady-state probability vector $x_s$ of this process.

(c.) Approximately how many bursts will it take for this process to be within 4 decimal places of accuracy of the steady-state?
