# Lower Bound on the Block-Diagonal SDP Relaxation for the Clique Number of the Paley Graph

Vlad Kobzar, joint work with

Yifan Wang

Yanling Shen

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

## Outline

- The clique number problem and the Paley graphs
- Compressed sensing and sparse recovery motivations
- Block-diagonal (L<sup>t</sup>), SOS and Lovasz-Schrivjer SDPs
- Our contributions
  - L<sup>t</sup> lower bounds via FK pseudomoments
  - Localization lower bounds, and relaxation-localization trade-off

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

Conclusion and future work

## Paley graph clique number

- Classic problem in number theory and additive combinatorics
- Connected to Ramsey theory, random matrices, computational complexity and optimization, to name a few research areas
- Links to deterministic restricted isometries in compressed sensing and sparse recovery

Ramsey

### Background

For any G = (V, E):

•  $K \subseteq V$  is a *clique* if each  $i, j \in K$  are adjacent

Clique number

 $\omega(G) =$  the size of a largest clique

I ⊆ V is an independence set if each i, j ∈ I are not adjacent
 Independence number

 $\alpha(G)$  = the size of a largest independence set

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

Finding  $\omega(G)$  and  $\alpha(G)$  is NP-hard for general graphs

# Paley graph

Connections to compressed sensing and sparse recovery

- SLOGAN: compressible high-dimensional signal can be recovered from very few measurements
- $x \in \mathbb{R}^n$  is *s*-sparse if it has no more than *s* nonzero entries
- When can you recover x exactly from few measurements y
- ▶ Sparse recovery experiment design of  $A \in \mathbb{C}^{m \times n}$

$$\begin{bmatrix} y \end{bmatrix} = \begin{bmatrix} & A & \end{bmatrix} \begin{bmatrix} x \\ x \end{bmatrix}$$

where

 $s < m \ll n$ 

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

## Restricted isometry property (RIP)

- Guarantees that sparse recovery is robust to noise
- ►  $A \in \mathbb{C}^{m \times n}$  satisfies RIP with distortion  $0 < \delta < 1$  if for any *s*-sparse *x*

$$(1-\delta)\|x\|^2 \le \|Ax\|_2^2 \le (1+\delta)\|x\|^2$$

Matrices with Gaussian i.i.d. entries satisfy RIP w.h.p. if

 $s \sim m/\log(n)$ 

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

#### Square root bottleneck

 Deterministic constructions based on controlling "spikeness" or "localization" (coherence) of rows achieve

$$s \approx \sqrt{m}$$

- ► Include those based on the eigenvectors corresponding to  $\lambda_1(A_{G_p})$  and  $\lambda_2(A_{G_p})$  [Arash Amini and Marvasti, 2015]
- A combinatorial construction overcomes this bottleneck with

$$s = \Omega(m^{rac{1}{2}+\epsilon})$$

for small  $\epsilon > 0$  [Bourgain et al., 2011b, Bourgain et al., 2011a]

 Accordingly, random constructions are abundant but deterministic constructions are hard to find ("hay in the haystack")

#### Paley matrices

 Matrices constructed from rows of the DFT matrix corresponding to QR's mod p [Bandeira et al., 2013] support

$$s\sim\sqrt{p}$$

 Conditioned on a conjecture about the # of edges in any subgraph of G<sub>p</sub> [Bandeira et al., 2016], these matrices support

$$s \sim p / \mathsf{polylog}(p)$$

 Unconditional [Kaplan et al., 2019] for signals with a certain sparse structure

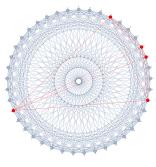

$$s = \Omega(m^{\frac{1}{2} + \frac{9}{40}})$$

A lower bound on ω(G<sub>p</sub>) would lead to a lower bound on the distortion constant δ

## Paley graph clique number

- Classic problem in number theory and additive combinatorics
- $G_p$  share similarities with Erdos-Renyi graphs  $\mathcal{G}(1/2, p)$
- ▶ Is  $\omega(G_p) = O(\text{polylog } p)$ , i.e., is  $G_p$  roughly a Ramsey graph?
- ▶ Note  $\omega(\mathcal{G}(1/2, n)) \sim 2 \log_2 n$

 $\omega(G_{41})=5$

## Existing bounds

 Upper bounds [Hanson and Petridis, 2021, Benedetto et al., 2021]

$$\omega(G_p) \leq (\sqrt{2p-1}+1)/2$$

- Improves on  $\sqrt{p}$  by a constant prefactor.
- Lower bound for infinitely many primes [Graham and Ringrose, 1990]

$$\log p \cdot \log \log \log p \leq \omega(G_p)$$

Conditioned on GRH [Montgomery, 1971],

$$\log p \cdot \log \log p \leq \omega(G_p)$$

Numerical experiments [Bachoc et al., 2014]

$$\omega(G_p) \approx \operatorname{polylog}(p)$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

#### Integer program

Easier to see in the context of the independence number  $\alpha(G)$ 

$$egin{aligned} &\omega(\mathit{G_p}) = \max_{x \in \mathbb{R}^p} \sum_i x_i \ & ext{ s.t. } x_i^2 = x_i ext{ for all } i \in V \ & ext{ } x_i x_j = 0 ext{ for all } \{i,j\} \in E \end{aligned}$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

- We focus on the clique problem ω(G) (i.e., take x<sub>i</sub>x<sub>j</sub> = 0 for all {i,j} ∉ E)
- It makes connections to A<sub>G<sub>p</sub></sub> more apparent

#### Nonconvex semidefinite matrix optimization

$$\max_{Y \in \mathbb{S}^{p+1 \times p+1}} \sum_{i \in \mathbb{Z}_p} Y_{\emptyset i}$$
  
s.t.  $Y_{ii}^2 = Y_{ii}$  for all  $i \in V$   
 $Y_{ij} = 0$  if  $\{i, j\} \notin E$   
 $Y \succeq 0, \ Y_{\emptyset \emptyset} = 1$   
rank $(Y) = 1$ 

This is equivalent to the previous program for ω(G<sub>p</sub>)
 Let y = (1, x<sub>1</sub>,..., x<sub>n</sub>) and reparametrize:

$$Y = yy^{T} = \begin{pmatrix} 1 & x_{1} & x_{2} & \dots & x_{p} \\ x_{1} & x_{1} & x_{1}x_{2} & \dots & x_{1}x_{p} \\ x_{2} & x_{1}x_{2} & x_{2} & \dots & x_{1}x_{p} \\ \vdots & & \ddots & \vdots \\ x_{p} & & & x_{p} \end{pmatrix}$$

## $SOS-2 = Lovasz-Schrivjer_0 = L^1$ convex relaxation

Then we drop the nonconvex constraints

$$\max \sum_{i \in V} y_i$$
  
s.t.y  $\in \mathbb{R}^p, Y \in \mathbb{R}^{p \times p}$   
 $Y_{ij} = 0 \text{ if } i \neq j, \{i, j\} \notin E$   
 $Y_{ii} = y_i, i \in V$   
 $\begin{pmatrix} 1 & y^\top \\ y & Y \end{pmatrix} \succeq 0$ 

One can show this is equivalent to the Lovász & function

### SOS / Laserre-Parrilo hierarchy

$$SOS_{2t}(G) = \max \sum_{i \in V} y_i$$
  
s.t.  $M_t(y) \succeq 0, y_0 = 1, y_{ij} = 0$  if  $\{i, j\} \in E$ .

## Sum of squares relaxations

- An open problem proposed by Mixon and Bandeira is whether the SOS-4 relaxation of the Paley graph clique number breaks this barrier
- Xu & Kunisky
  - provided numerical evidence that SOS<sub>4</sub>(G<sub>p</sub>) relaxation are O(p<sup>1/2-e</sup>)
  - proved an  $\Omega(p^{\frac{1}{3}})$  lower bound
- ► However, SOS<sub>4</sub>(G<sub>p</sub>) appears to be computationally intractable even for moderate p ≈ 250.
- Gvozdenovic et al. introduced a more computationally efficient block-diagonal hierarchy of SDPs (L<sup>t</sup>)

 $SOS_{2t}(G_p) \leq L^t(G_p)$

### Block Diagonal Hierarchy

▶ For  $T \in \mathcal{P}_{t-1}(V)$ , introduce M(T; y), a principal sub-matrix of  $M_t(y)$  indexed by  $\bigcup_{S \subseteq T} \{S, S \cup \{i\}, i \in V\}$ .

$$L^{t}(G) = \max \sum_{i \in V} y_{i}$$
$$M(T; y) \succeq 0 \ \forall \ |T| = t - 1$$
$$y_{0} = 1, y_{ij} = 0, \{i, j\} \in E.$$

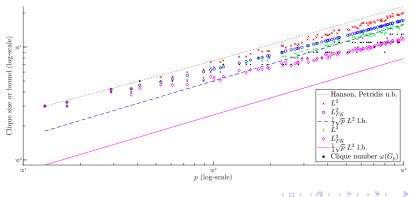

- Less computationally expensive than SOS<sup>2t</sup>(G).
- A relaxation of SOS because M<sub>t</sub>(y) ≥ 0 is requires every submatrix to be PSD
- Block-diagonalized by zeta matrices it is sufficient to use p+1×p+1 matrices in the constraints.

### Main result: Lower bound on $L^t(G_p)$

We proved the following lower bound

$$L^t(\overline{G}_p) \geq rac{\sqrt{p}}{2^{t-1}} + o(\sqrt{p}).$$

► This shows L<sup>t</sup> does not break √p bottleneck for fixed t, but may beat it if t(p) is a slowly increasing function of p.

500

#### Localization-relaxation trade-off

Localization G<sub>p,K</sub> of subgraphs induced on vertices K adjacent to all vertices in G<sub>p</sub> is another technique used to strengthen convex relaxations [Passuello, 2013, Magsino et al., 2019] and, more recently, spectral bounds on ω(G<sub>p</sub>) [Kunisky, 2023].

for any clique K of size a,

$$L^{t}(\overline{G}_{p,K}) \geq \frac{\sqrt{p}}{2^{a+t-1}} + o(\sqrt{p}).$$

► This shows L<sup>t</sup> does not break √p bottleneck for fixed t, but may beat it if a(p) is a slowly increasing function of p.

# Proof idea

- We construct a feasible point of L<sup>2</sup> using Feige-Krauthgamer (FK) pseudomoments, similarly to such construction in [Kunisky and Yu, 2022] for SOS<sub>2t</sub>.
- The FK program L<sup>2</sup><sub>FK</sub>(G<sub>p</sub>) corresponding to L<sup>2</sup>(G<sub>p</sub>) is defined by replacing A<sub>{0}</sub> with:

$$A_{\{0\}} = \begin{pmatrix} \frac{y_{\{0\}} & y_{\{0\}} & y_{\{0,1\}}(A_{G_p})_{0,1:end}}{y_{\{0\}} & y_{\{0\}} & y_{\{0,1\}}(A_{G_p})_{0,1:end}} \\ y_{\{0\}} & y_{\{0\}} & y_{\{0,1\}} \times \\ y_{\{0,1\}} \times & y_{\{0,1\}} \times \\ (A_{G_p})_{1:end,0} & (A_{G_p})_{1:end,0} \end{pmatrix} y_{\{0,1\}} diag(A_{G_p})_{1:end,0} + \alpha_3 M'$$

where M' is the indicator matrix of triangles in  $G_p$  of the form  $\{0, i, j\}$  for  $1 \le i, j < p$ , and reducing the number of scalar optimization variables  $y_{\{0,\alpha,\beta\}}$  corresponding to the orbits of triangles to the single  $\alpha_3 \in \mathbb{R}$ .

► Use the Schur complements to reduce the PSD constraints to a system of scalar inequalities for  $y_{\{0\}}$   $y_{\{0,1\}}$  and  $\alpha_3$ . Future direction - symmetries and upper bounds

- We plan to upper bound L<sup>2</sup> and L<sup>3</sup>, and therefore ω(G<sub>p</sub>), by constructing feasible points of the corresponding dual programs.
- Since the edges and the edges triples (triangles) form orbits under Aut(G<sub>p</sub>), the number of optimization variables is proportional to the number of the representatives of such orbits
- Since a Paley graph is edge-transitive, the representatives of such orbits are given by {0,1,β} where both β and β − 1 are squares in Z<sub>p</sub>; there are approximately (p − 5)/24 orbits.

► The upper bound problem can be reduced to a problem of studying the e.s.d of indicators of orbits as p → ∞
