D-MINIMAL EXPANSIONS OF THE REAL FIELD HAVE THE EXCHANGE PROPERTY*

CHRIS MILLER

Version: December 15, 2006

Throughout, \mathfrak{R} denotes a structure on \mathbb{R} . Definability is with respect to \mathfrak{R} . Given $A \subseteq \mathbb{R}$, dcl(A) denotes the definable closure of A, that is, the set of all A-definable points in \mathbb{R} .

 \mathfrak{R} has the Exchange Property if for all $A \subseteq \mathbb{R}$ and $x, y \in \mathbb{R}$:

 $y \in \operatorname{dcl}(A \cup \{x\}) \setminus \operatorname{dcl}(A) \Longrightarrow x \in \operatorname{dcl}(A \cup \{y\}).$

 \mathfrak{R} is **d-minimal** if for every $n \in \mathbb{N}$ and definable $A \subseteq \mathbb{R}^{n+1}$, there exists $N \in \mathbb{N}$ such that for every $x \in \mathbb{R}^m$, the fiber $\{t \in \mathbb{R} : (x,t) \in A\}$ either has interior or is a union of N (not necessarily distinct) discrete sets. (Recall that $Y \subseteq \mathbb{R}^m$ is **discrete** if for every $y \in Y$ there is an open box B such that $Y \cap B = \{y\}$.)

Proposition. If \mathfrak{R} is a d-minimal expansion of $(\mathbb{R}, +, \cdot)$, then it has the Exchange Property.

Proof. Let $A \subseteq \mathbb{R}$ and $x, y \in \mathbb{R}$ be such that $y \in \operatorname{dcl}(A \cup \{x\}) \setminus \operatorname{dcl}(A)$. Then there is an A-definable function $f \colon \mathbb{R} \to \mathbb{R}$ such that f(x) = y. By arguing as in the proof of [?, Theorem 3.3], there is an A-definable $S \subseteq \mathbb{R}$ such that S is closed and has no interior, and for every open interval $I \subseteq \mathbb{R} \setminus S$, the restriction $f \upharpoonright I$ is either constant or strictly monotone. By d-minimality, there exists $N \in \mathbb{N}$ such that S is a union of N discrete sets. The set of all isolated points of S is A-definable. Since $\mathbb{Q} \subseteq \operatorname{dcl}(\emptyset)$, every isolated point of S is A-definable. Hence (by an easy induction on N), each $s \in S$ is A-definable. Since $y \notin \operatorname{dcl}(A)$, we have $x \notin S$, so there is an A-definable open interval I about x such that $f \upharpoonright I$ is strictly monotone. Since the compositional inverse of $f \upharpoonright I$ is A-definable, $x \in \operatorname{dcl}(A \cup \{y\})$.

An examination of the proof shows that we needed neither d-minimality nor the field structure per se:

Corollary (of the proof). Suppose that $\langle is \emptyset$ -definable and dcl(\emptyset) is dense in \mathbb{R} —in particular, if \mathfrak{R} is an expansion of ($\mathbb{R}, \langle, +, 1\rangle$ —and every definable subset of \mathbb{R} either has interior or is a finite union of discrete sets. Then \mathfrak{R} has the Exchange Property.

Warning. It may appear that no use was made of working over \mathbb{R} , but this is not true: I do not know how to get the conclusion of the third sentence of the proof just from d-minimality (I use the Baire Category Theorem).
