Categorical analogies

Tensor categories categorify algebras.

| | |
|--|---|
| algebra A finite dimensional algebra center $Z(A)$ commutant $Z_B(A)$ of A in B | tensor category \mathcal{C} fusion category Drinfel'd center $\mathcal{Z}(\mathcal{C})$ commutant $\mathcal{Z}_{\mathcal{D}}(\mathcal{C})$ of \mathcal{C} in \mathcal{D} |
| $B(H)$ commutant $A' := Z_{B(H)}(A)$ von Neumann algebra $A = A''$ | $\text{Bim}(R)$, all bimodules commutant $\mathcal{C}' := \mathcal{Z}_{\text{Bim}(R)}(\mathcal{C})$ bicommutant category $\mathcal{C} \cong \mathcal{C}''$ |

Bicommutant categories categorify von Neumann algebras.

Today, we will prove the *categorified finite dimensional bicommutant theorem*.

Unitary fusion categories

We start with a unitary fusion category $\mathcal{C} \subset \text{Bim}(R)$.

- ▶ Have a system of bifinite bimodules and intertwiners
- ▶ The system is closed under
 - ▶ Finite direct sum: $x, y \in \mathcal{C} \Rightarrow x \oplus y \in \mathcal{C}$
 - ▶ Connes fusion: $x, y \in \mathcal{C} \Rightarrow x \boxtimes y \in \mathcal{C}$
 - ▶ Contragredient: $x \in \mathcal{C} \Rightarrow \bar{x} \in \mathcal{C}$
 - ▶ Taking sub-bimodules: $x \subset y \in \mathcal{C} \Rightarrow x \in \mathcal{C}$
- ▶ Finitely many isomorphism classes of irreducible bimodules.

Examples

- ▶ Start with a finite group G , and form $R \subset R \rtimes G$. The $R - R$ bimodules generated by $L^2(R \rtimes G)$ form $\text{Vec}(G)$.
- ▶ Given a finite index, finite depth subfactor $R \subset M$, the $R - R$ bimodules generated by $L^2(M)$ form a unitary fusion category.

Graphical calculus

Fix a finite set $\text{Irr}(\mathcal{C})$ of representatives of irreducibles.

- ▶ Morphisms $f : x \otimes y \rightarrow z$ are represented by coupons.
- ▶ For all $x, y, z \in \text{Irr}(\mathcal{C})$, $\text{Hom}(1, x \otimes y \otimes z)$ is a finite dimensional Hilbert space with inner product $\langle f, g \rangle = g^* \circ f$.

Choose dual bases:

$$e_i \in \text{Hom}(1, x \otimes y \otimes z) \text{ and } e^i \in \text{Hom}(1, \bar{z} \otimes \bar{y} \otimes \bar{x})$$

We represent the canonical element by colored nodes

$$\begin{array}{c} x \quad y \\ \diagdown \quad / \\ \bullet \\ | \\ z \end{array} \otimes \begin{array}{c} z \\ | \\ \bullet \\ / \quad \backslash \\ x \quad y \end{array} := \sqrt{d_x d_y d_z} \cdot \sum_i \begin{array}{c} x \quad y \\ | \quad | \\ \textcircled{e_i} \\ | \\ z \end{array} \otimes \begin{array}{c} z \\ | \\ \textcircled{e^i} \\ / \quad \backslash \\ x \quad y \end{array}$$

The canonical element is independent of choice of basis.

Important relations

$$\begin{array}{c} z \\ | \\ \text{---} \circ \text{---} \\ | \\ \text{---} \circ \text{---} \\ | \\ z \end{array} \begin{array}{c} x \\ | \\ \text{---} \circ \text{---} \\ | \\ \text{---} \circ \text{---} \\ | \\ y \end{array} = d_z^{-1} N_{x,y}^z \begin{array}{c} | \\ | \\ | \\ | \\ z \end{array} \quad \text{(Bigon 1)}$$

$$\begin{array}{c} z \\ | \\ \text{---} \circ \text{---} \\ | \\ \text{---} \circ \text{---} \\ | \\ z \end{array} \otimes \begin{array}{c} x \ y \\ \diagdown \ / \\ \text{---} \circ \text{---} \\ | \\ z \end{array} \otimes \begin{array}{c} z \\ | \\ \text{---} \circ \text{---} \\ | \\ x \ y \end{array} = d_z^{-1} \begin{array}{c} | \\ | \\ | \\ | \\ z \end{array} \otimes \begin{array}{c} x \ y \\ \diagdown \ / \\ \text{---} \circ \text{---} \\ | \\ z \end{array} \otimes \begin{array}{c} z \\ | \\ \text{---} \circ \text{---} \\ | \\ x \ y \end{array} \quad \text{(Bigon 2)}$$

$$\sum_{z \in \text{Irr}(\mathcal{C})} d_z \begin{array}{c} x \ y \\ \diagdown \ / \\ \text{---} \circ \text{---} \\ | \\ z \\ \diagdown \ / \\ \text{---} \circ \text{---} \\ | \\ x \ y \end{array} = \begin{array}{c} | \\ | \\ | \\ | \\ x \ y \end{array} \quad \text{(Fusion)}$$

$$\sum_{v \in \text{Irr}(\mathcal{C})} d_v \begin{array}{c} y \ z \\ \diagdown \ / \\ \text{---} \circ \text{---} \\ | \\ v \\ \diagdown \ / \\ \text{---} \circ \text{---} \\ | \\ w \ x \end{array} \otimes \begin{array}{c} \bar{z} \ \bar{y} \\ \diagdown \ / \\ \text{---} \circ \text{---} \\ | \\ \bar{v} \\ \diagdown \ / \\ \text{---} \circ \text{---} \\ | \\ \bar{x} \ \bar{w} \end{array} = \sum_{u \in \text{Irr}(\mathcal{C})} d_u \begin{array}{c} y \ z \\ \diagdown \ / \\ \text{---} \circ \text{---} \\ | \\ u \\ \diagdown \ / \\ \text{---} \circ \text{---} \\ | \\ w \ x \end{array} \otimes \begin{array}{c} \bar{z} \ \bar{y} \\ \diagdown \ / \\ \text{---} \circ \text{---} \\ | \\ \bar{u} \\ \diagdown \ / \\ \text{---} \circ \text{---} \\ | \\ \bar{x} \ \bar{w} \end{array} \quad \text{(I=H)}$$

We'll use Snyder convention and ignore all scalars.

Commutant \mathcal{C}' of \mathcal{C} in $\text{Bim}(R)$

The commutant $\mathcal{C}' \subset \text{Bim}(R)$ of $\mathcal{C} \subset \text{Bim}(R)$ has:

- ▶ Objects are pairs (X, e_X) where $X \in \text{Bim}(R)$, and e_X is a unitary half braiding with \mathcal{C}

$$e_{X,c} = \begin{array}{c} \diagup \\ X \quad \diagdown \\ \quad \quad \quad c \end{array} : X \boxtimes c \rightarrow c \boxtimes X$$

These half braidings must satisfy compatibility conditions.

- ▶ Morphisms $f : (X, e_X) \rightarrow (Y, e_Y)$ are bimodule maps $f : X \rightarrow Y$ which commute with the half braidings:

$$\begin{array}{c} \begin{array}{c} \diagup \\ X \quad \diagdown \\ \quad \quad \quad c \end{array} \begin{array}{c} \boxed{f} \\ \diagdown \\ \quad \quad \quad Y \end{array} = \begin{array}{c} \begin{array}{c} \boxed{f} \\ \diagdown \\ \quad \quad \quad X \end{array} \begin{array}{c} \diagup \\ \quad \quad \quad c \\ \quad \quad \quad Y \end{array} \end{array}$$

\mathcal{C}' is a tensor category, but it is usually not braided.

Functor $\text{Bim}(R) \rightarrow \mathcal{C}'$

We have a way to construct lots of objects in \mathcal{C}' .

$$\underline{\Delta} : \text{Bim}(R) \rightarrow \mathcal{C}' \quad \underline{\Delta}(\Lambda) = (\Delta(\Lambda), e_{\Delta(\Lambda)}) = (\Delta, e_{\Delta}).$$

$\Delta \in \text{Bim}(R)$ with unitary half braiding $e_{\Delta,a} : \Delta \boxtimes a \rightarrow a \boxtimes \Delta$.

$$\Delta := \bigoplus_{x \in \text{Irr}(\mathcal{C})} x \boxtimes \Lambda \boxtimes \bar{x}.$$

$$e_{\Delta,a} := \sum_{x,y \in \text{Irr}(\mathcal{C})} \begin{array}{c} a \quad y \Lambda \bar{y} \\ \diagdown \quad | \quad | \quad | \quad \diagup \\ \quad \quad \quad \bullet \quad \bullet \\ \quad \quad \quad | \quad | \\ x \Lambda \bar{x} \quad a \end{array}$$

Description of $\text{End}_{\mathcal{C}'}(\Delta)$

The map that sends $f = (f_a : \Lambda \boxtimes a \rightarrow a \boxtimes \Lambda)_{a \in \text{Irr}(\mathcal{C})}$ to

$$T_f := \sum_{a, x, y \in \text{Irr}(\mathcal{C})} \begin{array}{c} y \quad \Lambda \quad \bar{y} \\ | \quad | \quad | \\ \bullet \quad | \quad \bullet \\ \diagdown \quad \text{\scriptsize } f_a \quad / \\ | \quad | \quad | \\ x \quad \Lambda \quad \bar{x} \end{array} : \Delta \rightarrow \Delta$$

induces an isomorphism

$$\bigoplus_{a \in \text{Irr}(\mathcal{C})} \text{Hom}_{\text{Bim}(R)}(\Lambda \boxtimes a, a \boxtimes \Lambda) \cong \text{End}_{\mathcal{C}'}(\underline{\Delta}(\Lambda)).$$

Note $T_f \in \text{End}_{\mathcal{C}'}(\Delta)$ using the (I=H) Relation:

$$\sum_{a, x, y, z \in \text{Irr}(\mathcal{C})} \begin{array}{c} b \quad z \quad \Lambda \quad \bar{z} \\ \diagdown \quad | \quad | \quad | \\ y \quad \bullet \quad | \quad \bullet \\ \text{\scriptsize } f_a \quad | \quad \text{\scriptsize } a \\ | \quad | \quad | \\ x \quad \Lambda \quad \bar{x} \quad b \end{array} = \sum_{a, x, y, z \in \text{Irr}(\mathcal{C})} \begin{array}{c} b \quad z \quad \Lambda \quad \bar{z} \\ | \quad | \quad | \quad \diagdown \\ \bullet \quad \bullet \quad | \quad \bullet \\ y \quad \text{\scriptsize } a \quad | \quad \text{\scriptsize } \bar{y} \\ \text{\scriptsize } f_a \quad | \quad \text{\scriptsize } a \\ | \quad | \quad | \\ x \quad \Lambda \quad \bar{x} \quad b \end{array} .$$

Absorbing objects

Definition

An object Ω in a tensor category \mathcal{T} is *absorbing* if $\Omega \otimes t \cong \Omega \cong t \otimes \Omega$ for all $t \in \mathcal{T}$.

- ▶ Isomorphisms are not required to be natural or canonical.
- ▶ Absorbing objects are unique up to isomorphism if they exist.
- ▶ Taking $t = 1 \oplus 1$, we have $\Omega \cong \Omega \otimes (1 \oplus 1) \cong \Omega \oplus \Omega$.

Examples

- ▶ $\ell^2(\mathbb{N})$ is absorbing in the category of separable Hilbert spaces.
- ▶ $\ell^2(G) \otimes \ell^2(\mathbb{N})$ is absorbing in $\text{Rep}(G)$, G a countable group
- ▶ ${}_R L^2(R) \otimes \ell^2(\mathbb{N}) \otimes L^2(R)_R$ is absorbing in $\text{Bim}(R)$.

Absorbing objects of \mathcal{C}'

Absorbing objects of $\mathcal{T} \subset \text{Bim}(R)$ *control* half braidings of $\mathcal{T}' \subset \text{Bim}(R)$.

Theorem

If $\Omega \in \mathcal{T}$ is absorbing and $(X, e_X) \in \mathcal{T}'$, then e_X is completely determined by $e_{X, \Omega}$.

When \mathcal{C} is a unitary fusion category, \mathcal{C}' has absorbing objects.

Theorem

If $\Lambda \in \text{Bim}(R)$ is absorbing, then $\Delta \in \mathcal{C}'$ is absorbing.

- ▶ If $\Lambda \in \text{Bim}(R)$ is absorbing, then $\text{End}_{\mathcal{C}'}(\Delta)$ is a factor.
- ▶ $\text{End}_{\text{Bim}(R)}(\Lambda) \hookrightarrow \text{End}_{\mathcal{C}'}(\Delta)$ is a subfactor!

The main theorem

Recall \mathcal{C} is a unitary fusion category. The bicommutant \mathcal{C}'' allows infinite direct sums, so \mathcal{C} is not a bicommutant category.

Let $\mathcal{C} \otimes_{\text{Vec}} \text{Hilb}$ be the category obtained from \mathcal{C} by allowing infinite direct sums. (This is sometimes called the ind-category of \mathcal{C} .)

Theorem

$\mathcal{C} \otimes_{\text{Vec}} \text{Hilb}$ is a bicommutant category.

This theorem categorifies the following well-known result:

- ▶ A finite dimensional $*$ -algebra that can be faithfully represented on a Hilbert space is in fact a von Neumann algebra.

Corollary

\mathcal{C}' is also a bicommutant category.

Outline of the proof

There is an obvious fully faithful embedding $\mathcal{C} \otimes_{\text{Vec}} \text{Hilb} \hookrightarrow \mathcal{C}''$.

The proof of essential surjectivity has 3 main steps:

1. The underlying object X of an object $(X, e_X) \in \mathcal{C}''$ is of the form $X \cong \bigoplus_{c \in \text{Irr}(\mathcal{C})} c \otimes H_c$ for $H_c \in \text{Hilb}$.
2. Two objects (X, e_X^1) and (X, e_X^2) have the same half braiding with an absorbing object $\Omega \in \mathcal{C}'$, i.e., $e_{X, \Omega}^1 = e_{X, \Omega}^2$.
3. Absorbing objects uniquely determine half braidings.

Proof of 1.

- ▶ Start with $(X, e_X) \in \mathcal{C}''$.
- ▶ Take $\Lambda = L^2(R) \otimes L^2(R)$ and form $\Delta = \bigoplus_{c \in \text{Irr}(\mathcal{C})} c \otimes \bar{c} \in \mathcal{C}'$.
- ▶ Have a bimodule isomorphism $e : X \boxtimes \Delta \rightarrow \Delta \boxtimes X$.

$$e : \bigoplus_{c \in \text{Irr}(\mathcal{C})} X \boxtimes c \otimes \bar{c} \longrightarrow \bigoplus_{c \in \text{Irr}(\mathcal{C})} c \otimes \bar{c} \boxtimes X$$

- ▶ Isomorphism is R -linear for *four* distinct R -actions!
- ▶ Apply functor $\text{Hom}_{3^{\text{rd}}-R, 4^{\text{th}}-R}(L^2(R), -)$ to see

$$\begin{aligned} X &\cong \bigoplus_{c \in \text{Irr}(\mathcal{C})} \text{Hom}_{3^{\text{rd}}-R, 4^{\text{th}}-R}(L^2(R), X \boxtimes c \otimes \bar{c}) \\ &\cong \bigoplus_{c \in \text{Irr}(\mathcal{C})} \text{Hom}_{3^{\text{rd}}-R, 4^{\text{th}}-R}(L^2(R), c \otimes \bar{c} \boxtimes X) \\ &\cong \bigoplus_{c \in \text{Irr}(\mathcal{C})} c \otimes \underbrace{\text{Hom}_{R-R}(L^2(R), \bar{c} \boxtimes X)}_{H_c} \end{aligned}$$
