

# Jones' index rigidity theorem

## 1 Quantum Integers

**Definition 1.** Consider  $Q = \{e^{i\theta} \mid \theta \in (0, \frac{\pi}{2})\} \cup [1, \infty)$

For  $q \in Q$ , we define quantum  $n$  by

$$[n] = \frac{q^n - q^{-n}}{q - q^{-1}}.$$

Quantum integers satisfy the following formulas:

- $[1] = 1$
- $[2][1] = [2] = q + q^{-1}$
- $[2][n] = [n + 1] + [n - 1]$ .

**Lemma 2.** Suppose  $q = e^{i\theta}$  for some  $\theta \in (0, \frac{\pi}{2})$ , where  $\theta \neq \frac{2\pi}{2n}$  for some  $n \geq 3$ , i.e.,  $q$  is not a primitive  $(2n)$ -th root of unity for some  $n \geq 3$ . Let  $k \geq 2$  be minimal such that  $\theta > \frac{2\pi}{2(k+1)}$ . Then  $[1], [2] \dots, [k] > 0$ , but  $[k + 1] < 0$ .

*Proof.* Note that since  $q = e^{i\theta}$ ,

$$[j] = \frac{e^{ij\theta} - e^{-ij\theta}}{e^{i\theta} - e^{-i\theta}} = \frac{\sin(j\theta)}{\sin(\theta)}.$$

Since  $\sin(\theta) > 0$ , we only care about  $\sin(j\theta)$ . Since  $\frac{\pi}{k} > \theta > \frac{\pi}{k+1}$ , we have that  $\sin(1\theta), \dots, \sin(k\theta) > 0$ , but  $\sin((k + 1)\theta) < 0$ .  $\square$

**Remark 3.** Note that  $[n] = 0$  if and only if  $q$  is a  $(2n)$ -th root of unity. If  $q = e^{i\theta}$ , then  $[2] = q + q^{-1} = 2 \cos(\theta)$ .

## 2 The Temperley-Lieb algebras

**Definition 4.** For  $n \geq 0$ , let  $TL_n(q)$  be the complex vector space whose basis is the set of non-intersecting string diagrams (up to isotopy) on a rectangle with  $n$  boundary points on the top and bottom. For example, the basis for  $TL_3(q)$  is given by

On  $TL_n(q)$ , we define a multiplication by (the bilinear extension of) stacking boxes, removing the middle line segment, and smoothing the strings, and removing any closed loops and multiplying by a factor of  $[2]$ , e.g.

$$\begin{array}{|c|} \hline \text{Z} \\ \hline \end{array} \cdot \begin{array}{|c|} \hline \text{S} \\ \hline \end{array} = \begin{array}{|c|} \hline \text{S} \\ \hline \end{array} = [2] \begin{array}{|c|} \hline \text{S} \\ \hline \end{array}.$$

We define an involution by (the anti linear extension of) reflection about a horizontal line, e.g.

$$\begin{array}{|c|} \hline \text{Z} \\ \hline \end{array}^* = \begin{array}{|c|} \hline \text{S} \\ \hline \end{array}.$$

The multiplication and the adjoint make  $TL_n(q)$  a complex  $*$ -algebra.

**Proposition 5.** For  $i = 1, \dots, n - 1$ , the elements

$$E_i = \begin{array}{|c|} \hline \dots \\ \hline \text{Z} \\ \hline \dots \\ \hline \end{array}$$

satisfy the following relations:

$$(1) E_i^2 = \begin{array}{|c|} \hline \dots \\ \hline \text{Z} \\ \hline \dots \\ \hline \end{array} = [2] \begin{array}{|c|} \hline \dots \\ \hline \text{S} \\ \hline \dots \\ \hline \end{array} = [2]E_i = [2]E_i^*,$$

$$(2) E_i E_j = \begin{array}{|c|} \hline \dots \\ \hline \text{Z} \\ \hline \dots \\ \hline \end{array} = \begin{array}{|c|} \hline \dots \\ \hline \text{S} \\ \hline \dots \\ \hline \end{array} = E_j E_i \text{ if } |i - j| > 1, \text{ and}$$

$$(3) E_i E_{i\pm 1} E_i = \begin{array}{|c|} \hline \dots \\ \hline \text{Z} \\ \hline \dots \\ \hline \end{array} = \begin{array}{|c|} \hline \dots \\ \hline \text{S} \\ \hline \dots \\ \hline \end{array} = E_i.$$

**Definition 6.** The inclusion tangle

$$i_n = \begin{array}{|c|} \hline \dots \\ \hline \text{Z} \\ \hline \dots \\ \hline \end{array}$$

is a unital, injective  $*$ -algebra homomorphism  $TL_n(q) \rightarrow TL_{n+1}(q)$ .

The conditional expectation tangle

$$\mathcal{E}_{n+1} = \begin{array}{|c|} \hline \dots \\ \hline \text{Z} \\ \hline \dots \\ \hline \end{array}$$

is a surjective map of  $\mathbb{C}$ -vector spaces  $TL_{n+1}(q) \rightarrow TL_n(q)$ .

The trace tangle

defines a map  $TL_n(q) \rightarrow TL_0(q)$ . Note that  $TL_0(q) \cong \mathbb{C}$  via the map which sends the empty diagram to 1. Using  $\text{tr}_n$ , we can define a sesquilinear form on  $TL_n(q)$  by  $\langle x, y \rangle_n = \text{tr}_n(xy^*)$ .

Of course, the identity map  $\text{id}_n$  is given by the following diagram:

**Proposition 7.** *The maps  $i_n, \mathcal{E}_{n+1}, \text{tr}_n$ , and  $\text{id}_n$  satisfy the following relations:*

- (1)  $\mathcal{E}_{n+1} \circ i_n = [2] \text{id}_n$ ,
- (2)  $\text{tr}_{n+1} = \text{tr}_n \circ \mathcal{E}_{n+1}$ ,
- (3)  $(i_n \circ i_{n-1} \circ \mathcal{E}_n(x))E_n = E_n i_n(x)E_n$  for all  $x \in TL_n(q)$ ,
- (4)  $\text{tr}_n(xy) = \text{tr}_n(yx)$  for all  $x, y \in TL_n(q)$ ,
- (5) (Markov property)  $\text{tr}_{n+1}(i_n(x) \cdot E_n) = \text{tr}_n(x)$  for all  $x \in TL_n(q)$ , and
- (6)  $\text{tr}_n(\mathcal{E}_{n+1}(x) \cdot y) = \text{tr}_{n+1}(x \cdot i_n(y))$  for all  $x \in TL_{n+1}(q)$  and  $y \in TL_n(q)$ .

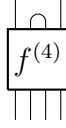

*Proof.* The proof is a good exercise in drawing diagrams and is left to the reader.  $\square$

### 3 The Jones-Wenzl projections

**Definition 8.** Let  $f^{(0)} \in TL_0(q)$  be the empty diagram. Let  $f^{(1)} \in TL_1(q)$  be the strand, i.e.,  $f^{(1)} = \begin{array}{|c|} \hline \square \\ \hline \end{array}$ . If  $[n+1] \neq 0$ , we inductively define

$$f^{(n+1)} = i_n(f^{(n)}) - \frac{[n]}{[n+1]} i_n(f^{(n)}) E_n i_n(f^{(n)}) = \begin{array}{|c|} \hline \dots \\ \hline \square \\ \hline \dots \\ \hline \end{array} - \frac{[n]}{[n+1]} \begin{array}{|c|} \hline \dots \\ \hline \square \\ \hline \dots \\ \hline \end{array} \begin{array}{|c|} \hline \dots \\ \hline \square \\ \hline \dots \\ \hline \end{array}.$$

**Proposition 9.** *Suppose  $[1], \dots, [n] \neq 0$  so that  $f^{(0)}, f^{(1)}, \dots, f^{(n)}$  are well-defined. Then  $f^{(n)}$  satisfies the following properties:*

(1) Capping any two strands on top of  $f^{(n)}$  gives zero, e.g.,  = 0,

(2)  $f^{(n)}$  is an orthogonal projection, i.e.,  $f^{(n)} = (f^{(n)})^* = (f^{(n)})^2$ ,

(3)  $\mathcal{E}_n(f^{(n)}) = \text{Diagram of } f^{(n)} \text{ with a loop on the top strand} = \frac{[n+1]}{[n]} f^{(n-1)}$ ,

(4)  $\text{tr}_n(f^{(n)}) = [n+1]$ , and

(5)  $(i_n(f^{(n)}))f^{(n+1)} = \text{Diagram of } f^{(n+1)} \text{ above } f^{(n)} = f^{(n+1)}(i_n(f^{(n)})) = \text{Diagram of } f^{(n)} \text{ above } f^{(n+1)} = f^{(n+1)}$ .

*Proof.* The proof is a simple induction on  $n$ . We show property (4) holds for  $f^{(n)}$  (assuming all the properties hold for  $f^{(n-1)}$ ), since we will use it below.

$$\begin{aligned} \text{tr}_n(f^{(n)}) &= \text{tr}_n(i_{n-1}(f^{(n-1)})) - \frac{[n-1]}{[n]} \text{tr}_n(i_{n-1}(f^{(n-1)})E_{n-1}i_{n-1}(f^{(n-1)})) \\ &= [2] \text{tr}_{n-1}(f^{(n-1)}) - \frac{[n-1]}{[n]} \text{tr}_{n-1}(f^{(n-1)}) \\ &= [2][n] - [n-1] \\ &= [n+1]. \end{aligned}$$

□

**Theorem 10** (Jones' index rigidity). *Suppose  $\langle \cdot, \cdot \rangle_j$  is positive semidefinite for all  $j \geq 0$ . Then either  $q \geq 1$ , or  $q$  is a primitive  $(2n)$ -th root of unity for some  $n \geq 3$ . Hence*

$$[2] = q + q^{-1} \in \left\{ 2 \cos \left( \frac{\pi}{n} \right) \mid n \geq 3 \right\} \cup [2, \infty).$$

*Proof.* If  $q$  is not of this form, then let  $k$  be as in Lemma 2. We see that since  $[1], [2], \dots, [k] \neq 0$ ,  $f^{(k)}$  is well-defined. However,

$$\langle f^{(k)}, f^{(k)} \rangle_k = \text{tr}_k(f^{(k)}) = [k+1] < 0,$$

which is a contradiction. □
