FRACTAL DIMENSION AND THE PERSISTENT HOMOLOGY OF RANDOM GEOMETRIC COMPLEXES

BENJAMIN SCHWEINHART

Abstract. We prove that the fractal dimension of a metric space equipped with an Ahlfors regular measure can be recovered from the persistent homology of random samples. Our main result is that if $x_1, \ldots, x_n$ are i.i.d. samples from a $d$-Ahlfors regular measure on a metric space, and $E_\alpha^0(x_1, \ldots, x_n)$ denotes the $\alpha$-weight of the minimum spanning tree on $x_1, \ldots, x_n$:

$$E_\alpha^0(x_1, \ldots, x_n) = \sum_{e \in T(x_1, \ldots, x_n)} |e|^\alpha,$$

then there exist constants $0 < C_1 \leq C_2$ so that

$$C_1 \leq n^{-\frac{d-\alpha}{d}} E_\alpha^0(x_1, \ldots, x_n) \leq C_2$$

with high probability as $n \to \infty$. In particular, $d$ can be recovered from the limit

$$\log \left( E_\alpha^0(x_1, \ldots, x_n) \right) / \log(n) \to (d - \alpha) / d.$$ 

This is a generalization of a result of Steele [63] from the non-singular case to the fractal setting. We also construct an example of an Ahlfors regular measure for which the limit $\lim_{n \to \infty} n^{-\frac{d-\alpha}{d}} E_\alpha^0(x_1, \ldots, x_n)$ does not exist with high probability, and prove analogous results for weighted sums defined in terms of higher dimensional persistent homology.

1. Introduction

The first precise notion of a fractal dimension was proposed by Hausdorff in 1918 [32, 38]. Since then, many other definitions have been put forward, including the box [13] and correlation [35] dimensions. These quantities do not agree in general, but coincide on a class of regular sets. Fractal dimension was popularized by Mandelbrot in the 1970s and 1980s [51, 50], and it has since found a wide range of applications in subjects including medicine [4, 47], ecology [36], materials science [24, 69], and the analysis of large data sets [5, 66]. It is also important in pure mathematics and mathematical physics, in disciplines ranging from dynamics [65] to probability [7].

Recently, there has been a surge of interest in applications of topology, and of persistent homology in particular. Several authors have proposed estimators of fractal
dimension defined in terms of minimum spanning trees and higher dimensional per-
sistent homology [2, 49, 53, 56, 67], and provided empirical evidence that those
quantities agreed with classical notions of fractal dimension. Here, we provide the
first rigorous justification for the use of random minimum spanning trees and higher
dimensional persistent homology to estimate fractal dimension.

We define a persistent homology dimension for measures (Definition 9) and prove
that it equals the Hausdorff dimension for a wide class of “regular” measures (Corol-
lary 10). In concurrent, separate work with J. Jaquette [42], we implement an al-
gorithm to compute this persistent homology dimension and provide computational
evidence that it performs as well or better than classical dimension estimation tech-
niques.

Informally, a set of “fractal dimension” \(d\) is self-similar in the sense that its “local
properties” measured at scale \(\epsilon\) scale as \(\epsilon^d\) or \(\epsilon^{-d}\) for some positive real number
\(d\) that may be non-integral. This is not well-defined in general, and there exist
“multifractals” for which different local properties give different values of \(d\). Here,
we assume a standard regularity hypothesis that implies that the fractal dimension
of a measure is well-defined in the sense that the various classical notions of fractal
dimension — including the Hausdorff, box-counting, and correlation dimensions —
coincide. This is done by taking the volumes of balls centered at points in our set as
the defining “local property.”

**Definition 1** ([8, 22]). A probability measure \(\mu\) supported on a metric space \(X\) is
d-Ahlfors regular if there exist positive real numbers \(c\) and \(\delta_0\) so that

\[
\frac{1}{c} \delta^d \leq \mu(B_\delta(x)) \leq c \delta^d
\]

for all \(x \in X\) and \(\delta < \delta_0\), where \(B_\delta(x)\) is the open ball of radius \(\delta\) centered at \(x\).

Ahlfors regularity is a common hypothesis used when studying geometry and analysis
in the fractal setting [22, 23, 44, 48, 55]. If \(\mu\) is \(d\)-Ahlfors regular on \(X\) then it is
comparable to the \(d\)-dimensional Hausdorff measure on \(X\), and the Hausdorff measure
is itself \(d\)-Ahlfors regular. Examples of Ahlfors regular measures include the natural
measures on the Sierpiński triangle and Cantor set, and, more generally, on any
self-similar subset of Euclidean space defined by an iterated function system whose
correct-dimensional Hausdorff measure is positive [1] (a weaker requirement than
the usual open set condition); a certain well-studied measure on the boundary of
certain hyperbolic groups including the fundamental group of a compact, negatively
curved manifold [20, 23]; and bounded probability densities on a compact manifold,
either with the intrinsic metric or one induced by an embedding in Euclidean space
(these are indeed “self-similar” sets). As such, our methods and results will be more general than previous papers on the absolutely continuous case. Standard arguments used in proofs for the non-singular case do not work here, and laws of large numbers that follow from them are false for some Ahlfors regular measures (as we will see in Counterexample 4 below).

We study the asymptotic behavior of random variables of the form

$$E^i_\alpha (x_1, \ldots, x_n) = \sum_{I \in PH_i(x_1, \ldots, x_n)} |I|^\alpha,$$

where \(\{x_j\}_{j \in \mathbb{N}}\) are i.i.d. samples from a probability measure \(\mu\) on a metric space, \(PH_i(x_1, \ldots, x_n)\) denotes the \(i\)-dimensional reduced persistent homology of the Čech or Vietoris–Rips complex of \(\{x_1, \ldots, x_n\}\), and \(|I|\) is the length of a persistent homology interval. Unless otherwise specified, our results apply to the persistent homology of either the Čech or Vietoris–Rips complex, though the constants may differ. The case where \(i = 0\) and \(\mu\) is absolutely continuous is already well-studied, under a different guise: if \(T(x_1, \ldots, x_n)\) denotes the minimum spanning tree on \(x_1, \ldots, x_n\) and

$$E_\alpha (x_1, \ldots, x_n) = \sum_{e \in T(x_1, \ldots, x_n)} |e|^\alpha,$$

then

$$E_\alpha (x_1, \ldots, x_n) = E^0_\alpha (x_1, \ldots, x_n)$$

where persistent homology is taken with respect to the Vietoris–Rips complex.

In 1988, Steele [63] proved the following celebrated result.

**Theorem 2** (Steele). Let \(\mu\) be a compactly supported probability measure on \(\mathbb{R}^m\), \(m \geq 2\), and let \(\{x_n\}_{n \in \mathbb{N}}\) be i.i.d. samples from \(\mu\). If \(0 < \alpha < m\),

$$\lim_{n \to \infty} n^{-\frac{m-\alpha}{m}} E_\alpha^0 (x_1, \ldots, x_n) \to c(\alpha, m) \int_{\mathbb{R}^m} f(x)^{(m-\alpha)/m} dx$$

with probability one, where \(f(x)\) is the probability density of the absolutely continuous part of \(\mu\), and \(c(\alpha, m)\) is a positive constant that depends only on \(\alpha\) and \(m\).

Steele wrote [63]:

One feature of Theorem 2 that should be noted is that if \(\mu\) has bounded support and \(\mu\) is singular with respect to Lebesgue measure, then we have with probability one that \(E_\alpha^0 (x_1, \ldots, x_n) = o \left( n^{(d-\alpha)/d} \right)\). Part of the appeal of this observation is the indication that the length of the minimum spanning tree is a measure of the dimension of the support.
of the distribution. This suggests that the asymptotic behavior of the minimum spanning tree might be a useful adjunct to the concept of dimension in the modeling applications and analysis of fractals; see, e.g., [50].

However, despite many subsequent sharper and more general results for non-singular measures on Euclidean space [3, 43, 70] and Riemannian manifolds [21], little is known about the asymptotic properties of random minimum spanning trees for singular measures. As far as we know, the only previous result toward that end is that of Kozma, Lotker and Stupp [44], who proved that if $\mu$ is a $d$-Ahlfors regular measure with connected support, then the length of the longest edge of a minimum spanning tree on $n$ i.i.d. points sampled from $\mu$ is $\approx (\log (n) / n)^{1/d}$, where the symbol $\approx$ denotes that the ratio between the two quantities is bounded between two positive constants that do not depend on $n$. They also raised the possibility that analogous asymptotics hold for the alpha-weight of a minimum spanning tree, which we prove here in Theorem 3.

More recently, as the field of stochastic topology has matured, several studies have examined the properties of the higher dimensional persistent homology of random geometric complexes defined by absolutely continuous measures on Euclidean space [6, 10, 9, 28, 68]. Most relevantly, Divol and Polonik [27] proved a strong law of large numbers akin to Steele’s theorem for the persistent homology of points sampled from bounded, absolutely continuous probability densities on $[0,1]^m$. In the non-persistent setting, several authors have investigated the homology of random geometric complexes on manifolds [11, 12, 25, 54]. However, as far as we know, the current work is the first to study persistent homology of random geometric complexes beyond the world of absolutely continuous measures on $\mathbb{R}^m$ with convex support (with the exception of our unpublished manuscript [59], which has largely been subsumed into the current work). With these broader hypotheses, we encounter difficult geometric issues related to non-locality and non-triviality of persistent homology, which we discuss below.

A relationship between persistent homology and fractal dimension has been observed in several experimental studies. In 1991, Weygaert, Jones, and Martinez [67] proposed using the asymptotics of $E_\alpha(x_1, \ldots, x_n)$ to estimate the generalized Hausdorff dimensions of chaotic attractors. The PhD thesis of Robins, which was arguably one of the first publications in the field of topological data analysis, studied the scaling of Betti numbers of fractals and proved results for the 0-dimensional persistent homology of disconnected sets [56]. In joint work with Robert MacPherson, we proposed a dimension for probability distributions of geometric objects based on persistent homology in 2012 [49]. Note that the quantities studied in that paper and in the
thesis of Robins measure the complexity of a shape rather than the fractional dimension. Most recently, Adams et al. [2] defined a persistent homology dimension for measures in terms of the asymptotics of $E_1^1(x_1,\ldots,x_n)$. Their computational experiments helped to inspire this work. We study a modified version of their dimension here (Definition 9), and find hypotheses under which it agrees with the Ahlfors dimension (Corollary 10).

In the extremal setting, Kozma, Lotker and Stupp [45] defined a minimum spanning tree dimension for a metric space $M$ in terms of the behavior of $E_0^\alpha(Y)$ as $Y$ ranges over all subsets of $M$, and proved that it equals the upper box dimension. In 2018, we generalized this concept to higher dimensional persistent homology and established hypotheses under which it agrees with the upper box dimension [60]. In the course of this work, we investigated extremal questions about the number of persistent homology intervals of a set of $n$ points; these questions are also important in the probabilistic context, as we describe below.

1.1. Our Results for Minimum Spanning Trees. Our main result is:

**Theorem 3.** Let $\mu$ be a $d$-Ahlfors regular measure on a metric space, and let $\{x_n\}_{n \in \mathbb{N}}$ be i.i.d. samples from $\mu$. If $0 < \alpha < d$, then

$$E_0^\alpha(x_1,\ldots,x_n) \approx n^{d-\alpha}$$
with high probability as $n \to \infty$, where the symbol $\approx$ denotes that the ratio of the two quantities is bounded between positive constants that do not depend on $n$.

We provide a proof of this result using the language of minimum spanning trees (rather than persistent homology) in Section 3. The special case where $\mu$ is a measure on Euclidean space is also a consequence of either Theorems 5 or 8 below.

The hypotheses we require to prove Theorem 3 and our other results below are somewhat weaker than Ahlfors regularity. In particular, the proofs of our upper bounds only require that $M_\delta(\mu) = O(\delta^{-d})$, where $M_\delta(\mu)$ is the maximal number of disjoint balls of radius $\delta$ centered at points of supp $\mu$. Also, the proofs of our lower bounds require that the uniform bounds in Equation 1 are satisfied on a set of positive measure, but not necessarily at every point in the support of $\mu$. However, a regularity hypothesis on the underlying measure is necessary. Some definitions of fractals include the chaotic attractors studied in Section 4 of our computational paper [42]. Our computations suggest that for several examples and each $\alpha > 0$ there is a different value of $d_\alpha$ so that $E_\alpha^0(y_1, \ldots, y_n) \approx n^{d_\alpha - \alpha}$ (i.e. that the measure is “multifractal”). In particular, we could not replace $d$ in the previous theorem with, say, the upper box or Hausdorff dimension of the support.

Our next result shows that a sharper law of large numbers as in Theorem 2 is false in general for Ahlfors regular measures.

**Counterexample 4.** Let $d = \log(2) / \log(3)$ and $0 < \alpha < d$. There exists a $d$-Ahlfors regular measure $\mu$ on $[0, 1]$ so that $\lim_{n \to \infty} n^{-\frac{d_\alpha}{d}} E_\alpha^0(x_1, \ldots, x_n)$ does not converge in probability.

In particular, we construct an example of a $d$-Ahlfors regular measure where $n^{-\frac{d_\alpha}{d}} E_\alpha^0(x_1, \ldots, x_n)$ oscillates between two positive real numbers with high probability. We provide a brief description of the counterexample here, and a complete proof in A. The construction can easily be modified to produce a counterexample of any dimension $d$ for any $d \in (0, 1)$ as described at the end of A, but we concentrate on the case $d = \log(2) / \log(3)$ for clarity.

Recall that the standard middle-thirds Cantor set $C$ is constructed as the intersection of a nested sequence of closed sets $T_1 \supset T_2 \supset \ldots$, where $T_k$ consists of $2^k$ disjoint intervals of length $(\frac{1}{3})^k$. Our counterexample will resemble $C$ at some scales, and $C$ rescaled by $\frac{5}{7}$ at others (see Figure 2). It will be supported on another nested sequence of of closed sets $S_1 \supset S_2 \ldots$. To construct the counterexample, we suppose that $\lim_{n \to \infty} n^{-\frac{d_\alpha}{d}} E_\alpha^0(y_1, \ldots, y_n) := c$ exists in probability, where $\{y_j\}_{j \in \mathbb{N}}$ are i.i.d. samples from the natural measure on $C$. We set $S_k = T_k$ for all sufficiently small
Figure 2. A rough depiction of the construction of Counterexample 4, where the size of each row is shown relative to the standard middle thirds Cantor set $C$ at the same scale. At larger scales, it resembles $C$ (first row). At a smaller scale, we shrink the pieces of the set by $\frac{5}{7}$ relative to $C$ (second row) resulting in structure that resembles $C$ rescaled by $\frac{5}{7}$ when zooming in further (third row). Even smaller, we re-expand pieces of the structure by $\frac{7}{5}$ relative to $C$ (fourth row) so that at finer scales it resembles $C$ again (fifth row). We repeat this process, resulting in a structure that alternates between resembling $C$ and $\frac{5}{7}C$ at different length-scales.

$k$ which ensures that, to a certain point, $n^{-\frac{d-\alpha}{d}}E_0^0(x_1, \ldots, x_n)$ also approaches $c$. At smaller length-scales $S_k$ instead consists of $2^k$ intervals of length $\frac{5}{7} \left(\frac{1}{3}\right)^k$, and we will show that $n^{-\frac{d-\alpha}{d}}E_0^0(x_1, \ldots, x_n)$ will dip down toward $\left(\frac{5}{7}\right)^\alpha c$. We repeat this inductively, resulting in quantities that oscillate between $c$ and $\left(\frac{5}{7}\right)^\alpha c$.

1.2. Our Results for Higher Dimensional Persistent Homology. As we noted in our earlier paper [60], proving asymptotic results for higher dimensional persistent
homology is challenging due to extremal questions about the number of persistent homology intervals of a finite point set. While a minimum spanning tree on \( n \) points always has \( n - 1 \) edges, a set of \( n \) points may have trivial \( PH_i \) for all \( i > 0 \), and there exist families of finite metric spaces for which the number of persistent homology intervals grows faster than linearly in the number of points.

To prove upper bounds for the asymptotics of \( E_\alpha^i \) for \( i > 0 \), we require either extremal or probabilistic control of the number of persistent homology intervals of a set of \( n \) points. Families of point sets in Euclidean space with more than a linear number of persistent homology intervals exist \([34, 60]\), but are considered somewhat pathological. As far as we know, the Upper Bound Theorem \([62]\) on the number of faces of a neighborly polytope provides the best extremal upper bound for the number of persistent homology intervals of the \( \text{\v Cech} \) complex of a finite subset of \( \mathbb{R}^m \):

\[
|PH_i(x_1, \ldots, x_n)| = \begin{cases} 
O\left(n^{i+1}\right) & i < \left\lfloor \frac{m}{2}\right\rfloor \\
O\left(n^{\left\lfloor \frac{m+1}{2}\right\rfloor}\right) & i \geq \left\lfloor \frac{m}{2}\right\rfloor 
\end{cases}
\]

For the Vietoris–Rips complex of points in Euclidean space, we \([60]\) showed that

\[
|PH_1(x_1, \ldots, x_n)| = O(n)
\]

by modifying an argument of Goff \([34]\). A different extremal question arises in the process of proving lower bounds for \( E_\alpha^i \). In particular, a subset \( \mathbb{R}^m \) must have dimension above a certain non-triviality constant \( \gamma_i^m \) (defined in Section 6.2) to guarantee the existence of subsets with non-trivial \( i \)-dimensional persistent homology. Note that \( \gamma_i^m \) may depend on whether persistent homology is taken with respect to the \( \text{\v Cech} \) complex or Vietoris–Rips complex. Unless otherwise noted, that dependence is left implicit. We showed that \( \gamma_1^m < m - 1/2 \) for the \( \text{\v Cech} \) complex in our previous paper \([60]\).

The proofs of the upper bounds in the next two theorems work for Ahlfors regular measures on arbitrary metric spaces, but the lower bound requires that the measure is defined on a subset of Euclidean space.

**Theorem 5.** Let \( \mu \) be a \( d \)-Ahlfors regular measure on \( \mathbb{R}^m \) with \( d > \gamma_i^m \), and let \( \{x_n\}_{n \in \mathbb{N}} \) be i.i.d. samples from \( \mu \). If there are positive real numbers \( D \) and \( a \) so that

\[
|PH_i(x_1, \ldots, x_n)| < Dn^a 
\]

for all finite subsets of \( \text{supp} \ \mu \), and \( 0 < \alpha < ad \), then there are real numbers \( 0 < \zeta < Z \) so that

\[
\zeta n^{d-\alpha \over d} \leq E_\alpha^i(x_1, \ldots, x_n) \leq Z n^{ad-\alpha \over d}
\]
with high probability, as \( n \to \infty \). In fact, the upper bound holds with probability one.

The upper bound is shown in Proposition 27, and the lower bound in Proposition 41. The following is a corollary, using our previous results on \( \gamma_1^2 \) and the fact that the Alpha complex of a set of \( n \) points in \( \mathbb{R}^2 \) has \( O(n) \) faces.

**Corollary 6.** Let \( \mu \) be a \( d \)-Ahlfors regular measure on \( \mathbb{R}^2 \), and let \( \{x_n\}_{n \in \mathbb{N}} \) be i.i.d. samples from \( \mu \). If \( 0 < \alpha < d \). If \( d > 1.5 \), \( 0 < \alpha < d \), and persistent homology is taken of the ˇČech complex, then

\[
E^1_{\alpha}(x_1, \ldots, x_n) \approx n^{d-\alpha}
\]

with high probability as \( n \to \infty \). In fact, the upper bound holds with probability one.

Another corollary, based on our results on the Rips complex [60], is

**Corollary 7.** Let \( \mu \) be a \( d \)-Ahlfors regular measure on \( \mathbb{R}^m \), and let \( \{x_n\}_{n \in \mathbb{N}} \) be i.i.d. samples from \( \mu \). If persistent homology is taken of the Rips complex, \( d > \gamma_1^m \), and \( 0 < \alpha < d \), then

\[
E^1_{\alpha}(x_1, \ldots, x_n) \approx n^{d-\alpha}
\]

with high probability as \( n \to \infty \). In fact, the upper bound holds with probability one.

For \( i > 0 \) and \( m > 2 \), we show better upper bounds for \( d \)-Ahlfors regular measures for which the expectation and variance of \( |PH_i(x_1, \ldots, x_n)| \) scale linearly and sub-quadratically, respectively. These quantities can be measured in practice, allowing one to determine whether higher dimensional persistent homology would be suitable for dimension estimation in applications.

**Theorem 8.** Let \( \mu \) be a \( d \)-Ahlfors regular measure on \( \mathbb{R}^m \) so that \( d > \gamma_1^m \), and let \( \{x_n\}_{n \in \mathbb{N}} \) be i.i.d. samples from \( \mu \). If

\[
\mathbb{E}(|PH_i(x_1, \ldots, x_n)|) = O(n) \quad \text{and} \quad \operatorname{Var}(|PH_i(x_1, \ldots, x_n)|) / n^2 \to 0
\]

and \( 0 < \alpha < d \), then there are real numbers \( 0 < \lambda < \Lambda \) so that

\[
\lambda n^{d-\alpha} \leq E^i_{\alpha}(x_1, \ldots, x_n) \leq \Lambda n^{d-\alpha} \log(n)^{\frac{\alpha}{d}}
\]

with high probability, as \( n \to \infty \).

The upper and lower bounds are shown in Propositions 32 and 41, respectively. Many of our other results can be viewed as special cases of this theorem, including Corollaries 6 and 7 and the particular case of Theorem 3 where the measure is supported.
on Euclidean space. More generally, although there are few rigorous results on the scaling of the number of persistent homology intervals in higher dimensions, computational results indicate that these hypotheses hold broadly — see the Appendix. Also, Stemeseder [64] showed that any positive, continuous probability density on the \( m \)-dimensional Euclidean sphere satisfies the hypothesis on the expected number of intervals, and the uniform measure on the sphere satisfies the hypothesis on the variance. However, we think these are interesting hypotheses not because they are easy to prove but because they can be estimated in data analysis.

1.3. Dimension Estimation. As we noted earlier, several authors have proposed to use persistent homology for dimension estimation. Here, we provide the first proof that these methods recover a classical fractal dimension, under certain hypotheses.

We define a family of \( PH_i \) dimensions of a measure, one for each real number \( \alpha > 0 \) and \( i \in \mathbb{N} \):

**Definition 9.**

\[
dim_{PH_i}^\alpha (\mu) = \frac{\alpha}{1 - \beta},
\]

where

\[
\beta = \limsup_{n \to \infty} \frac{\log \left( \mathbb{E} \left( E_{\alpha}^i (x_1, \ldots, x_n) \right) \right)}{\log (n)}.
\]

That is, \( \dim_{PH_i}^\alpha (\mu) \) is the unique real number \( d \) so that

\[
\limsup_{n \to \infty} \mathbb{E} \left( E_{\alpha}^i (x_1, \ldots, x_n) \right) n^{-\frac{k\alpha}{k}}
\]
equals \( \infty \) for all \( k < d \), and is bounded for \( k > d \). The case \( \alpha = 1 \) is very closely related to the dimension studied by Adams et al. [2], and agrees with it if defined.

Theorem 2 [63] implies that if \( \mu \) is a compactly supported, non-singular probability measure on \( \mathbb{R}^m \), then \( \dim_{PH_0} (\mu) = m \) for \( 0 < \alpha < m \). Similarly, the results of Divol and Polonik [27] show that if \( \mu \) is a bounded probability measure on the cube in \( \mathbb{R}^m \), then \( \dim_{PH_i} (\mu) = m \) for \( 0 < \alpha < m \) and \( 0 \leq i < m \).

The following is a corollary of our theorems on the asymptotic behavior of \( E_{\alpha}^i \):

**Corollary 10.** If \( \mu \) is a \( d \)-Ahlfors regular measure on a metric space and \( 0 < \alpha < d \) then

\[
\dim_{PH_0} = d.
\]
Furthermore, if \( \mu \) is defined on \( \mathbb{R}^m \), \( d > \gamma_m \), and
\[
\mathbb{E} (|PH_i (x_1, \ldots, x_n)|) = O (n) \quad \text{and} \quad \text{Var} (|PH_i (x_1, \ldots, x_n)|) / n^2 \to 0,
\]
then
\[
\dim_{PH_i} \alpha = d.
\]
This result is weaker than our main theorems, and it can be proven with weaker hypotheses. For example, the upper bound \( \dim_{PH_0} \alpha (\mu) \leq d \) holds if the hypothesis of \( d \)-Ahlfors regularity is replaced by the requirement that the upper box dimension of the support of \( \mu \) is equal to \( d \).

**Proposition 11.** Let \( \mu \) be a measure on a bounded metric space \( X \), and let \( \dim_{box} (X) \) be the upper box dimension of \( X \) (defined below). If \( \alpha < \dim_{box} (X) \) then
\[
\dim_{PH_0} \alpha (\mu) \leq \dim_{box} (X).
\]

In separate experimental work (joint with J. Jaquette), we implement an algorithm to compute the persistent homology dimensions and compare its practical performance below to classical techniques for estimating fractal dimension, such as box-counting and the estimation of the correlation dimension. The persistent homology dimension (for \( i = 0 \)) performs about as well as the correlation dimension, both in terms of the convergence rate and speed of computation, and significantly better than the box dimension. [42] Our results here imply that the computational estimates in [42] will converge with high probability as the number of samples goes to infinity for several of the examples considered. These include the \( PH_0 \) dimension of the Cantor dust, Cantor set cross an interval, Sierpiński triangle, and Menger sponge, and the \( PH_1 \) dimensions of the Cantor set cross an interval and the Sierpiński triangle.

1.4. **A Conjecture.** We conjecture that if the persistent homology of the support of an Ahlfors regular measure is trivial, then the Lebesgue measure can be replaced with the \( d \)-dimensional Hausdorff measure \( \mathcal{H}^d \) in Theorem 2. Note that this would exclude Counterexample 4.

**Conjecture 12.** Let \( \mu \) be a \( d \)-Ahlfors regular measure on a metric space \( M \) and let \( \{x_n\}_{n \in \mathbb{N}} \) be i.i.d. samples from \( \mu \). If \( PH_0 (\text{supp} \ \mu) \) is trivial and \( 0 < \alpha < d \), then
\[
\lim_{n \to \infty} n^{-d-\alpha} E_0 (x_1, \ldots, x_n) \to c_0 (\alpha, d) \int_M f (x)^{(d-\alpha)/d} \text{dx}
\]
with probability one, where \( f (x) \) is the probability density of the absolutely continuous part of \( \mu \) with respect to the \( d \)-dimensional Hausdorff measure \( \mathcal{H}^d \) and \( c_0 (\alpha, d) \) is a continuous function of \( \alpha \) and \( d \).
Furthermore, if \( \mu \) is supported on \( \mathbb{R}^m \), \( d > \gamma_i^m \), and \( \text{PH}_i(\text{supp } \mu) \) is trivial then
\[
\lim_{n \to \infty} n^{-\frac{d-\alpha}{d}} E^n_i(x_1, \ldots, x_n) \to c_i(\alpha, d) \int_M f(x)^{(d-\alpha)/d} \, dx
\]
with probability one, where \( f(x) \) is the probability density of the absolutely continuous part of \( \mu \) with respect to the \( d \)-dimensional Hausdorff measure \( \mathcal{H}^d \) and \( c_i(\alpha, d) \) is a continuous function of \( \alpha \) and \( d \).

2. Preliminaries

We introduce notation and lemmas that will be used throughout the paper. Lemma 14 controls the asymptotics of the maximal number of disjoint balls centered at points in the support of an Ahlfors regular measure, and will be applied in many of our arguments. In Section 2.3, we define occupancy indicators in terms of collections of subsets of a metric space, and prove a weak law of large numbers for them. Later in the paper, we will use these occupancy indicators to define events implying the existence of a minimum spanning tree edge or persistent homology interval of a certain length.

2.1. Notation. In the following, \( X \) will denote a metric space and \( x \) will denote a finite point set with an unspecified number of elements. Furthermore, \( x_n \) will be shorthand for a finite point set \( \{x_1, \ldots, x_n\} \subset X \) containing \( n \) points. If the measure \( \mu \) is obvious from the context, \( \{x_j\}_{j \in \mathbb{N}} \) will be a collection of independent random variables with common distribution \( \mu \). Finally, we will use symbols with the “mathcal” font (i.e. \( \mathcal{A}, \mathcal{B}, \ldots \)) for collections of sets.

2.2. Ahlfors Regularity and Ball-counting. Let \( X \) be a metric space, and let \( M_\delta(X) \) be the maximal number of disjoint open balls of radius \( \delta \) centered at points of \( X \). The upper box dimension is defined in terms of the asymptotic properties of \( M_\delta(X) \).

**Definition 13.** Let \( X \) be a bounded metric space. The upper box dimension of \( X \) is
\[
dim_{\text{box}}(X) = \limsup_{\delta \to 0} \frac{\log(M_\delta(X))}{-\log(\delta)}.
\]
If \( X \) admits a \( d \)-Ahlfors regular measure, we can control the behavior of \( M_\delta(X) \).

**Lemma 14** (Ball-counting Lemma). If \( \mu \) is a is \( d \)-Ahlfors regular measure supported on a metric space \( X \) then
\[
\frac{1}{c} 2^{-d} \delta^{-d} \leq M_\delta(X) \leq c \delta^{-d}
\]
for all $\delta < \delta_0$, where $c$ and $\delta_0$ are the constants given in Definition 1.

**Proof.** Let $\{x_j\}_{j=1}^{M_\delta(X)}$ be the centers of a maximal set of disjoint balls of radius $\delta$ centered at points of $X$.

$$1 = \mu(X) \geq \sum_{j=1}^{M_\delta(\mu)} \mu(B_\delta(x_j)) \text{ by disjointness} \geq \frac{1}{c} \delta^d M_\delta(\mu) \text{ by Ahlfors regularity} \implies M_\delta(\mu) \leq c\delta^{-d}.$$  

The maximality of $\{B_\delta(x_i)\}_{i=1}^{M_\delta(\mu)}$ implies that the balls of radius $2\delta$ centered at the points $\{x_i\}$ cover $X$. It follows that

$$1 = \mu(X) \leq \sum_{j=1}^{M_\delta(X)} \mu(B_{2\delta}(x_j)) \leq c2^d \delta^d M_\delta(X) \text{ by Ahlfors regularity} \implies M_\delta(X) \geq \frac{1}{c} 2^{-d} \delta^{-d},$$

as desired. \qed

2.3. **Occupancy Indicators.** Our strategy for proving lower bounds for the asymptotic behavior of $E_\alpha(x_1, \ldots, x_n)$ will be to define certain **occupancy indicators** that imply the existence of a persistent homology interval (or minimum spanning tree edge) whose length is bounded away from zero.  

If $A$ and $B$ are sets define

$$\delta(A, B) = \begin{cases} 0 & A \cap B = \emptyset \\ 1 & A \cap B \neq \emptyset \end{cases} .$$

Also, if $A$ is a set and $\mathcal{B}$ is a collection of sets define the occupancy indicator

$$\Xi(x, A, \mathcal{B}) = \begin{cases} 1 & \delta(A, x) = 0 \text{ and } \delta(B, x) = 1 \forall B \in \mathcal{B} \\ 0 & \text{otherwise} \end{cases} .$$
All occupancy indicators considered in this paper will satisfy $A \cap B = \emptyset$ for all $B \in \mathcal{B}$, and $B_1 \cap B_2 = \emptyset$ for all $B_1, B_2 \in \mathcal{B}$ so that $B_1 \neq B_2$. We say that two occupancy indicators $\Xi(x, A_1, \mathcal{B})$ and $\Xi(x, A_2, \mathcal{C})$ (where $x$ is the same sample for each) are disjoint if

$$\left( A_1 \cup \bigcup_{B \in \mathcal{B}} B \right) \cap \left( A_2 \cup \bigcup_{C \in \mathcal{C}} C \right) = \emptyset.$$ 

An $n, p, q, r$-bounded occupancy indicator is a random variable of the form $\Xi(x_n, A, \mathcal{B})$, where $\mathcal{B}$ is a collection of at least $r$ sets, and $x_n$ is a collection of $n$ independent random variables with common distribution $\nu$ satisfying

$$\nu(A) \leq q/n \quad \text{and} \quad \nu(B) \geq p/n \quad \forall B \in \mathcal{B}.$$ 

If the above conditions on $\nu$ and the number of sets in $\mathcal{B}$ hold with equality, we say that $\Xi(x_n, A, \mathcal{B})$ is a $n, p, q, r$-uniform occupancy indicator.

Disjoint $n, p, q, r$-uniform occupancy indicators satisfy a weak law of large numbers as $n \to \infty$.

**Lemma 15.** Let $r, a > 0$, and $0 < p, q < 1$. Also, for each $n \in \mathbb{N}$ let $X_1^n, \ldots, X_{[an]}^n$ be disjoint $n, p, q, r$-uniform occupancy indicators. If $Y_n = \frac{1}{n} \sum_{j=1}^{[an]} X_j^n$, then

$$\lim_{n \to \infty} Y_n = \gamma$$

in probability, where $\gamma = ae^{-q} (1 - e^{-p})^r$.

**Proof.** First, we compute the limiting expectation of the events $X_j^n$ as $n \to \infty$:

$$\mathbb{E}(X_j^n) = \mathbb{P}(X_j^n = 1) = \left(1 - \frac{q}{n}\right)^n \sum_{j=0}^r (-1)^j \binom{r}{j} \left(1 - j \frac{p/n}{1 - q/n}\right)^n$$

by inclusion-exclusion. Therefore

$$\lim_{n \to \infty} \mathbb{E}(X_j^n) = e^{-q} \left(\sum_{k=0}^r (-1)^k \binom{r}{k} e^{-kp}\right) = e^{-q} (1 - e^{-p})^r$$

where we factored the second term in the middle equation using the binomial theorem. Thus $\lim_{n \to \infty} \mathbb{E}(Y_n) = \gamma$ by linearity of expectation.
A similar computation shows that if $j \neq k$,

$$\lim_{n \to \infty} \mathbb{E} \left( X_j^n X_k^n \right) = e^{-2q} \left( 1 - e^{-p} \right)^{2r}.$$ 

It follows that

$$\lim_{n \to \infty} \text{Cov} \left( X_j^n, X_k^n \right) = \lim_{n \to \infty} \left( \mathbb{E} \left( X_j^n X_k^n \right) - \mathbb{E} \left( X_j^n \right) \mathbb{E} \left( X_k^n \right) \right) = 0.$$

Therefore

$$\text{Var} \left( Y_n \right) = \frac{1}{n^2} \left( \sum_{j=1}^{\lfloor an \rfloor} \text{Var} \left( X_j \right) + 2 \sum_{j=1}^{\lfloor an \rfloor} \sum_{i=1}^{j-1} \text{Cov} \left( X_j^n, X_k^n \right) \right)$$

$$\sim \frac{a}{n} \text{Var} \left( X_1^n \right) + a \frac{n^2 - n}{n^2} \text{Cov} \left( X_1^n, X_2^n \right)$$

$$\leq \frac{a}{n} + a \left( 1 - \frac{1}{n} \right) \text{Cov} \left( X_1^n, X_2^n \right)$$

also converges to 0 as $n$ goes to $\infty$.

Let $\epsilon > 0$ and $0 < \rho < 1$. Choose $N$ sufficiently large so that

$$\left| \mathbb{E} \left( Y_n \right) - \gamma \right| < \epsilon/2 \quad \text{and} \quad \text{Var} \left( Y_n \right) < \frac{\epsilon^2 \rho}{4}$$

for all $n > N$. If $n > N$,

$$\mathbb{P} \left( \left| Y_n - \gamma \right| > \epsilon \right) \leq \mathbb{P} \left( \left| Y_n - \mathbb{E} \left( Y_n \right) \right| > \epsilon/2 \right)$$

$$\leq \mathbb{P} \left( \left| Y_n - \mathbb{E} \left( Y_n \right) \right| > \frac{1}{\sqrt{\rho}} \sqrt{\text{Var} \left( Y_n \right)} \right)$$

$$\leq \rho$$

by Chebyshev’s Inequality. \(\Box\)

The occupancy indicators we define below will not be uniform, but we can use the previous lemma to bound them. To do so, we require a standard lemma on non-atomic measures [41, 61].

**Lemma 16.** If $\mu$ is a non-atomic measure on a metric space $Y$, and $0 < a < \mu \left( Y \right)$ then there exists $Y_0 \subset Y$ so that $\mu \left( Y_0 \right) = a$. 
Lemma 17. Let $r, a > 0$, $0 < p, q < 1$, and $s_n \geq \lfloor an \rfloor$ for all $n \in \mathbb{N}$. Also, for each $n \in \mathbb{N}$ let $X^n_1, \ldots, X^n_{s_n}$ be disjoint $n, p, q, r$-bounded occupancy indicators. Under these hypotheses, there is a $\gamma > 0$ so that

$$\lim_{n \to \infty} \frac{1}{n} \sum_{j=1}^{s_n} X^n_j \geq \gamma$$

with high probability.

Proof. Let $a_0 = \min \left( a, \frac{1}{p+q} \right)$, $1 \leq j \leq \lfloor a_0 n \rfloor$, and

$$X^n_j = \Xi \left( x^n, A^n_j, B^n_j \right).$$

$\nu$ is non-atomic, so by the previous lemma we can find a subset $\hat{B}$ of each set $B \in B^n_j$ so that $\nu \left( \hat{B} \right) = p/n$. Let

$$\hat{B}^n_j = \left\{ \hat{B} : B \in B^n_j \right\} \quad \text{and} \quad D_n = \bigcup_{j=1}^{\lfloor a_0 n \rfloor} \hat{B}.$$ 

We will show that there are disjoint sets $\hat{A}^n_1, \ldots, \hat{A}^n_{\lfloor a_0 n \rfloor}$ so that $A^n_j \subseteq \hat{A}^n_j \subseteq D^n_c$ and $\nu \left( \hat{A}^n_j \right) = q/n$ for $j = 1, \ldots, \lfloor a_0 n \rfloor$. Let $\hat{D}_n = D^n_c \cup \bigcup_j A^n_j$. The maximum index of $j$ is $\lfloor a_0 n \rfloor$ and $a_0 (p+q) \leq 1$ so

$$\nu \left( \hat{D}_0 \right) \geq \sum_{j=1}^{\lfloor a_0 n \rfloor} \left( \frac{q}{n} - \nu \left( A^n_j \right) \right).$$

Applying the previous lemma to $\nu \big|_{\hat{D}_n}$ gives a $C_1 \subseteq \hat{D}_n$ with $\nu \left( C_1 \right) = q/n - \nu \left( A^n_1 \right)$, so if $\hat{A}^n_1 = C_1 \cup A^n_1$ then $A^n_1 \subseteq \hat{A}^n_1 \subseteq \hat{D}_n$ and $\nu \left( \hat{A}^n_1 \right) = q/n$. Assuming we have found $\hat{A}^n_1, \ldots, \hat{A}^n_k$ we can apply the same argument to $\nu \big|_{\hat{D}_n \setminus \cup_{j=1}^{k} A^n_j}$ to find $\hat{A}^n_{k+1}$.

Let

$$\hat{X}^n_j = \Xi \left( x^n, \hat{A}^n_j, \hat{B}^n_j \right).$$

By construction, $X^n_j = 1 \implies \hat{X}^n_j = 1$ so $\frac{1}{n} \sum_{j=1}^{s_n} X^n_j$ stochastically dominates $\frac{1}{n} \sum_{j=1}^{\lfloor a_0 n \rfloor} \hat{X}^n_j$. Applying the Lemma 15 to the latter sum implies the desired result. \qed
3. The Proofs for Minimum Spanning Trees

We prove the upper and lower bounds in Theorem 3 in Sections 3.1 and 3.2 below. First, we sketch both proofs. If \( x \) is a finite metric space, let \( T(x) \) denote the minimum spanning tree on \( x \), and let \( p(x, \delta) \) be the number of edges of \( T(x) \) of length greater than \( \delta \).

To prove the upper bound, we begin by controlling \( p(x, \delta) \) in terms of the maximal number of disjoint balls of radius \( \delta/2 \) centered at points of \( x_n \) (Lemma 19). Combining this with the asymptotics we found in the ball-counting lemma above (Lemma 14) gives that \( p(x_n, \delta) \leq C \delta^{-d} \) for some constant \( C > 0 \) and all \( x_n \subset X \). We convert this into a bound on \( E^\alpha_{\delta}(x_n) \) by integrating (Lemma 20) and using that a minimum spanning tree on \( n \) points has \( n - 1 \) edges, yielding the upper bound in Theorem 3 (Proposition 21).

For the lower bound, we define an occupancy indicator that implies the existence of a minimum spanning tree edge of length at least \( \delta \), by requiring that a ball of radius \( \delta \) is occupied and its annulus of radii \((\delta, 2\delta)\) is not (Lemma 22 and the preceding text). Taking a collection of these indicators for a maximal set of disjoint balls of radius \( 2n^{-1/d} \) and applying Lemma 17 gives that

\[
p(x_n, n^{-1/d}) \geq \gamma n
\]

with high probability as \( n \to \infty \) for some \( \gamma > 0 \) (Lemma 23). Summing over edges of length exceeding \( n^{-1/d} \) proves the lower bound in Theorem 3 (Proposition 24).

We use the next lemma in our proofs of both the upper and lower bounds. Let \( G_{x, \epsilon} \) be the graph with vertex set \( x \) so that \( x_1 \) and \( x_2 \) are connected by an edge if and only if \( d(x_1, x_2) < \epsilon \) (this is the one-skeleton of the Vietoris-Rips complex on \( x \)). The following is a corollary of Kruskal’s algorithm.

**Lemma 18.**

\[
p(x, \epsilon) = \beta_0(G_{x, \epsilon}) - 1
\]

where \( \beta_0(G_{x, \epsilon}) \) is the number of connected components of \( G_{x, \epsilon} \).

3.1. Proof of the Upper Bound in Theorem 3.

**Lemma 19.** Let \( X \) be a metric space and suppose that there are positive real numbers \( D \) and \( d \) so that

\[
M_{\delta}(X) \leq D \delta^{-d}
\]
for all $\delta > 0$, where $M_\delta(X)$ is the maximal number of disjoint open balls of radius $\delta$ centered at points of $X$ (as defined in the previous section). Then

$$p(x, \delta) < D2^{-d} \delta^{-d}$$

for all finite subsets $x$ of $X$ and all $\delta > 0$.

Proof. Let $x \subset X$ and $\delta > 0$. Also, let $y$ consist of the centers of a maximal set of disjoint balls of radius $\delta/2$ centered at points of $x$. The maximality of $y$ implies that for every $x \in x$ there exists a $y \in y$ so that $d(x, y) < \delta$. In particular, every connected component of $G_{x, \delta}$ has a vertex that is an element of $y$. Therefore,

$$p(x, \delta) = \beta_0(G_{x, \delta}) - 1 \leq |y| - 1 \leq D(\delta/2)^{-d} \leq 2^{-d}D\delta^{-d}.$$  

□

The previous lemma controls of the number of MST edges of length greater than $\epsilon$. We can use this to prove an upper bound for $E_{0, x_n}^\alpha$ via the following lemma of Cohen-Steiner et al. [19].

**Lemma 20.** Let $J \subset \mathbb{R}_+$ be a bounded set of positive real numbers and let

$$J_\epsilon = \{ j \in J : j > \epsilon \} .$$

If

$$|J_\epsilon| \leq f(\epsilon) < \infty$$

for all $\epsilon > 0$ then

$$\sum_{j \in J_\epsilon} j^\alpha \leq \epsilon^\alpha f(\epsilon) + \alpha \int_{\delta=\epsilon}^{\max J} f(\delta) \delta^{\alpha-1} d\delta$$

for all $\alpha > 0$. Furthermore, if $|J| \leq f(0) < \infty$ then

$$\sum_{j \in J} j^\alpha \leq \alpha \int_{\delta=0}^{\max J} f(\delta) \delta^{\alpha-1} d\delta .$$

(3)
Proof. For completeness, we reproduce the proof in [19]. $\sum_{j \in J} j^\alpha$ can be expressed as an integral involving the distributional derivative of $|J_\delta|$. Applying integration by parts yields:

$$\sum_{j \in J} j^\alpha = \int_\delta^\infty \frac{\partial |J_\delta|}{\partial \delta} \delta^\alpha d\delta$$

$$= \left[ \delta^\alpha \right]_{\delta=\epsilon}^{\infty} + \alpha \int_\epsilon^\infty |J_\delta| \delta^{\alpha-1} d\delta$$

$$= \epsilon^\alpha |J_\epsilon| + \alpha \int_\epsilon^{\sup J} |J_\delta| \delta^{\alpha-1} d\delta$$

$$\leq \epsilon^\alpha f(\epsilon) + \alpha \int_\epsilon^{\sup J} f(\delta) \delta^{\alpha-1} d\delta.$$

\qed

Combining the previous two lemmas gives an extremal upper bound for $E_0^\alpha(x_n)$ that, when combined with Lemma 14, implies the upper bound for Theorem 3.

Proposition 21. Let $X$ be a metric space and suppose that there are positive real numbers $D$ and $d$ so that

$$M_\delta(X) \leq D \delta^{-d}$$

for all $\delta > 0$. If $0 < \alpha < d$, then there exists a $D_\alpha > 0$ so that

$$E_\alpha^0(x_n) \leq D_\alpha n^{\frac{d-\alpha}{d}}$$

for all $n$ and all collections $x_n$ of $n$ points in $X$. Furthermore, there exists a $D_d > 0$ so that

$$E_d^0(x_n) \leq D_d \log(n)$$

for all $n$ and all collections $x_n$ of $n$ points in $X$.

Proof. Rescale $X$ if necessary so that its diameter is less than 1, and let

$$\kappa = \frac{1}{2} \left( \frac{D}{n - 1} \right)^{1/d}.$$

The previous lemma implies that

$$p(\{x_n\}, \epsilon) \leq 2^{-d} D \epsilon^{-d}.$$ 

Furthermore,

$$p(\{x_n\}, \epsilon) \leq n - 1.$$
because a minimum spanning tree on \( n \) points has \( n - 1 \) edges. Combining these yields that
\[
p(\{x_n\}, \epsilon) \leq f(\epsilon)
\]
where
\[
f(\epsilon) = \min\left(n - 1, 2^{-d}D\epsilon^{-d}\right) = \begin{cases} 
  n - 1 & \epsilon \leq \kappa \\
  2^{-d}D\epsilon^{-d} & \epsilon \geq \kappa 
\end{cases}
\]
We have that Applying Lemma 20 to the set of edge lengths of the minimum spanning tree on \( x_n \) yields
\[
E_\alpha^0(x_n) = \sum_{e \in T(x_n)} |c|^\alpha 
\]
\[
\leq \alpha \int_{\delta=0}^{1} f(\delta) \delta^{\alpha-1} d\delta 
\]
by Eqn. 3
\[
= (n - 1) \int_{\delta=0}^{\kappa} \alpha \delta^{\alpha-1} d\delta + \alpha 2^{-d}D \int_{\delta=\kappa}^{1} \delta^{\alpha-d-1} d\delta 
\]
by Eqn. 4
\[
= (n - 1) [\delta^\alpha]_{\delta=0}^{\kappa} - \frac{\alpha}{d-\alpha} 2^{-d}D [\delta^{\alpha-d}]_{\delta=\kappa}^{1} 
\]
\[
= (n - 1) \kappa^\alpha + \frac{\alpha}{d-\alpha} 2^{-d}D (\kappa^{\alpha-d} - 1) 
\]
\[
= 2^{-\alpha}D^{\frac{\alpha}{2}} \left( 1 + D \frac{\alpha}{d-\alpha} \right) (n - 1) \frac{d-\alpha}{d-\alpha} - \frac{\alpha}{d-\alpha} 2^{-d}D 
\]
\[
\leq D_\alpha n^{\frac{d-\alpha}{d}} ,
\]
where
\[
D_\alpha = 2^{-\alpha}D^{\frac{\alpha}{2}} \left( 1 + D \frac{\alpha}{d-\alpha} \right) .
\]
The result for \( \alpha = d \) follows from a similar computation.

We now prove the upper bound in Theorem 3.

_Proof of the Upper Bound in Theorem 3._ Let \( \mu \) be a \( d \)-Ahlfors regular measure and \( 0 < \alpha < d \), and let \( X \) be the support of \( \mu \). By Lemma 14 there is a \( c > 0 \) so that
\[
M_\delta(X) \leq c \delta^{-d}
\]
for all \( \delta > 0 \). Therefore, by the previous lemma there exists a \( D_\alpha > 0 \) so that
\[
E_\alpha^0(x_n) \leq D_\alpha n^{\frac{d-\alpha}{d}}
\]
for all collections of \( n \) points \( x_n \subset X \).
Proposition 21 also implies Proposition 11, that the $PH_0$ dimension of a measure is bounded above by the upper box dimension (Definition 13) of its support, even if it is not Ahlfors regular.

**Proof of Proposition 11.** Let $\mu$ be a measure on a metric space $X$, $d = \dim_{\text{box}}(X)$ be the upper box dimension of $X$, and $\alpha < d < d_0$. By Definition 13 there is a $D > 0$ so that

$$M_\delta(X) \leq D\delta^{-d_0}$$

for all sufficiently small $\delta$. Therefore, by Proposition 21, there is a $D_\alpha > 0$ so that

$$E_\alpha^0(x_n) \leq D_\alpha n^{\frac{d_0-\alpha}{d_0}}$$

for all sets of $n$ points $x_n \subseteq X$.

Then

$$\beta := \limsup_{n \to \infty} \frac{\log (E_\alpha^i(x_n))}{\log (n)} \leq \frac{\log \left(n^{\frac{d_0-\alpha}{d_0}}\right)}{\log (n)} = \frac{d_0 - \alpha}{d_0}$$

and, recalling Definition 9,

$$\dim_{PH_\alpha^\ell} (\mu) = \frac{\alpha}{1 - \beta} \leq \frac{\alpha}{1 - (d_0 - \alpha)/d_0} = d_0,$$

where we have used that $\frac{d_0-\alpha}{d_0} > 0$. This inequality holds for any $d_0 > d$, so

$$\dim_{PH_\alpha^\ell} (\mu) \leq d = \dim_{\text{box}}(X),$$

as desired. \( \square \)

3.2. **Proof of the Lower Bound in Theorem 3.** Our strategy to prove a lower bound for the asymptotics of $E_\alpha^0(x_n)$ is to define random variables in terms of occupancy patterns of disjoint balls of radius $2r$. This will in turn allow us to count the number of minimum spanning tree edges of length at least $r$.

Let $M$ be a metric space and let $\mu$ be a $d$-Ahlfors regular measure with support $M$. If $B$ is a ball of radius $2r$ centered at a point $y \in M$ and $x$ is a finite subset of $M$, define

$$\omega(B, x) = \Xi(x, B \setminus B_r(y), \{B_r(y)\}).$$

That is, $\omega(B, x) = 1$ if $x$ intersects $B_r(y)$ but not the annulus centered at $y$ with radii $r$ and $2r$. 

Figure 3. The red balls on the right all satisfy $\omega(B, x) = 1$, which guarantees that the minimum spanning tree on the left has at least three edges whose length exceeds $r$.

**Lemma 22.** Let $B$ be a set of disjoint balls of radius $2r$ centered at points of $M$, and let $x$ be a finite subset of $M$. Then

$$p(x, r) \geq \sum_{B \in B} \omega(B, x) - 1.$$  

**Proof.** This is an immediate consequence of Lemma 18. See Figure 3. □

Next, we take $B$ to be a maximal set of disjoint balls of radius $2n^{-1/d}$ and use Lemma 17 to provide a lower bound for $p(x_n, n^{-1/d})$.

**Lemma 23.** There is a positive real number $\gamma > 0$ so that

$$p(x_n, n^{-1/d}) \geq \gamma n$$

with high probability as $n \to \infty$.

**Proof.** Fix $n \in \mathbb{N}$ and let $\epsilon = n^{-1/d}$. Let $B^n_1, \ldots, B^n_{s_n}$ be a maximal collection of disjoint balls of radius $2\epsilon$ centered at points of $X$, and let $y^n_j$ be the center of $B^n_j$ for $j = 1, \ldots, s_n$. 

Set

$$p = \frac{1}{c} \quad \text{and} \quad q = 2^d c - \frac{1}{c}.$$
where $c$ is the constant appearing in the definition of Ahlfors regularity (Definition 1). By that definition,
\[
\mu \left( B_{c\epsilon} \left( y_j^n \right) \right) \geq p \epsilon^d = \frac{p}{n}
\]
and
\[
\mu \left( B_j^n \setminus B_{c\epsilon} \left( y_j^n \right) \right) \leq c \left( 2\epsilon \right)^d - \frac{1}{c} \epsilon^d = \frac{q}{n}.
\]
Also, Lemma 14 implies that
\[
s_n \geq \frac{1}{c} 2^{-d} 2\epsilon^{-d} = \frac{1}{c} 2^{-2d} n.
\]
Therefore, the occupancy indicators $\omega \left( B_j^n, x_n \right), \ldots, \omega \left( B_{s_n}^n, x_n \right)$ satisfy the hypotheses of Lemma 17 and
\[
\lim_{n \to \infty} \frac{1}{n} \sum_{j=1}^{s_n} \omega \left( B_j^n, x_n \right) \geq \gamma
\]
with high probability as $n \to \infty$. Combining this with Lemma 22 gives the desired result.

The lower bound in Theorem 3 follows quickly.

**Proposition 24.** Let $\mu$ be a $d$-Ahlfors regular measure on a metric space $M$. If \( \{x_j\}_{j \in \mathbb{N}} \) are i.i.d. samples from $\mu$, and $\gamma$ is as given in the previous lemma, then
\[
\lim_{n \to \infty} n^{-d-\alpha/d} E_0^\alpha \left( x_n \right) \geq \gamma
\]
with high probability.

**Proof.** We have that
\[
\lim_{n \to \infty} n^{-d-\alpha/d} E_0^\alpha \left( x_n \right) \geq \lim_{n \to \infty} n^{-d-\alpha} \left( n^{-1/d} \right)^\alpha p \left( x_n, n^{-1/d} \right)
\]
\[
\geq \lim_{n \to \infty} n^{-d-\alpha} n^{-\alpha/d} \left( \gamma n \right)
\]
\[
= \gamma
\]
with high probability as $n \to \infty$. \qed
Persistent Homology

We provide a brief introduction to the persistent homology \cite{29} of a filtration, loosely following \cite{60}. For a more in-depth survey refer to, e.g., \cite{14, 15, 30, 31, 33}. A filtration of topological spaces is a family \( \{ X_\epsilon \}_{\epsilon \in I} \) of topological spaces indexed by an ordered set \( I \), with inclusion maps \( X_\epsilon \subset X_{\epsilon'} \) for all pairs of indices \( \epsilon_1 < \epsilon_2 \). For example, if \( X \) is a subset of a metric space \( M \), the \( \epsilon \)-neighborhood filtration of \( X \), \( \{ X_\epsilon \}_{\epsilon \geq 0} \), is the family of \( \epsilon \)-neighborhoods of \( X \), together with inclusion maps \( X_\epsilon \subset X_{\epsilon'} \) for \( \epsilon_1 < \epsilon_2 \). See Figure 1. If \( X \) is a subset of Euclidean space, this construction is homotopy equivalent to the Čech complex of \( X \). The Čech complex of a subset \( X \) of a metric space is the simplicial complex defined by 

\[(x_1, \ldots, x_n) \in C(X, \epsilon) \quad \text{if} \quad \bigcap_{j=1}^n B_\epsilon(x_j) \neq \emptyset.\]

Note that the Čech complex depends on the ambient metric space. For example if \( p_1, p_2, p_3 \) are the vertices of an acute triangle \( \mathbb{R}^m \) and the ambient space is \( \mathbb{R}^m \), then the 2-simplex \( (p_1, p_2, p_3) \) will enter \( C(X, \epsilon) \) when \( \epsilon \) equals the circumradius of the triangle. If the ambient space is \( \{p_1, p_2, p_3\} \), the simplex \( (p_1, p_2, p_3) \) will enter the complex when \( \epsilon \) equals the maximum pairwise distance between the three points.

In Euclidean space, the Alpha complex of a finite set \( x \) is filtration on the Delaunay triangulation on \( x \). We do not define the Alpha complex here; see \cite{29} for a definition.

Another common construction is the Vietoris–Rips complex: if \( Y \) is a metric space, let \( V(Y, \epsilon) \) be the simplicial complex defined by

\[(y_1, \ldots, y_n) \in V(Y, \epsilon) \quad \text{if} \quad d(y_j, y_k) < \epsilon \quad \text{for} \quad j, k = 1, \ldots, n.\]

The family \( \{ V(Y, \epsilon) \}_{\epsilon > 0} \) together with inclusion maps for \( \epsilon_1 < \epsilon_2 \) is a filtration indexed by the positive real numbers. As noted earlier, all of our results apply to both the Čech and Vietoris–Rips complexes except for Corollaries 6 and 7, though the constants may differ. We will suppress the dependence of persistent homology on the underlying filtration, unless otherwise noted.

The persistent homology module of a filtration is the product \( \prod_{\epsilon \in I} H_i(X_\epsilon) \), together with the homomorphisms \( j_{\epsilon_0, \epsilon_1} : H_i(X_{\epsilon_0}) \to H_i(X_{\epsilon_1}) \) for \( \epsilon_0 < \epsilon_1 \), where \( H_i(X_\epsilon) \) denotes the reduced homology of \( X_\epsilon \) with coefficients in a field. If the rank of \( i_{\epsilon_0, \epsilon_1} \) is finite for all \( \epsilon_0 < \epsilon_1 \), a hypothesis satisfied by all filtrations considered in this paper \cite{17, 15} — the persistent homology module decomposes canonically into a set of interval modules \cite{16, 71}. We denote the collection of these intervals as.
If \( x \) is a finite metric space and persistent homology is taken with respect to the Vietoris–Rips complex, Kruskal’s algorithm implies that there is a length-preserving bijection between intervals of \( PH_0(x) \) and the edges of the minimum spanning tree on \( x \). The same is true if persistent homology is taken with respect to the Čech complex if the ambient space is \( \mathbb{R}^m \), except that an interval is matched with an edge of twice its length.

**4.1. Properties of Persistent Homology.** Let \( X \) be a metric space. For each \( \epsilon > 0 \), let \( PH^\epsilon_i(X) \) denote the set of intervals of \( PH_i(X) \) of length greater than \( \epsilon \):

\[
PH^\epsilon_i(X) = \{ I \in PH_i(X) : |I| > \epsilon \} .
\]

Also, define

\[
p_i(X, \epsilon) = |PH^\epsilon_i(X)| .
\]

If \( X, Y \subset X \), let \( d_H(X, Y) \) denote the Hausdorff distance between \( X \) and \( Y \):

\[
d_H(X, Y) = \inf \{ \epsilon \geq 0 : Y \subseteq X_\epsilon \text{ and } X \subset Y_\epsilon \} .
\]

Also, let \( d(X, Y) \) be the infimal distance between pairs of points, one in each set:

\[
d(X, Y) = \inf_{x \in X, y \in Y} d(x, y) .
\]

We use the following properties of persistent homology in our proofs:

1. **Stability**: If \( d_H(X, Y) < \epsilon \), there is an injection
   \[
   \eta : PH^{2\epsilon}_i(X) \to PH_i(Y)
   \]
   so that if \( \eta((b_0, d_0)) = (b_1, d_1) \) then
   \[
   \max (|b_0 - b_1|, |d_0 - d_1|) < \epsilon .
   \]
   In particular,
   \[
p_i(X, 2\epsilon + \delta) \leq p_i(Y, \delta)
   \]
   for all \( \delta \geq 0 \). \cite{17, 18}

2. **Additivity for well-separated sets**: If \( X_1, \ldots, X_n \subset M \) and
   \[
d(X_j, X_k) > \max (\text{diam } X_j, \text{diam } X_k) (1 - \delta_{j,k}) \quad \forall j, k
   \]
then
\[ p_i (\cup_j X_j, \epsilon) \geq \sum_j p_i (X_j, \epsilon) . \]

(3) **Translation invariance:** \( PH_i (X) = PH_i (X + t) \) for all \( t \in \mathbb{R}^m \).

(4) **Scaling:** For all \( \rho > 0 \),
\[ PH_i (\rho X) = \{(\rho b, \rho d) : (b, d) \in PH_i (X)\} . \]

We use property (1) in our proofs of both the upper and lower bounds in Theorems 5 and 8, and property (2) for our proof of the lower bound. For these results, we also require a non-triviality property (as in Definition 35) and an upper bound for the number of \( i \)-dimensional persistent homology intervals of a set of \( n \) points.

4.2. **A Lemma.** If \( X \) is a metric space, let \( F^i_\alpha (X, \epsilon) \) denote the \( \alpha \)-weighted sum of the persistent homology intervals of \( X \) of length greater than \( \epsilon \):
\[ F^i_\alpha (X, \epsilon) = \sum_{I \in PH^i_\epsilon (X)} |I|^\alpha . \]

We will use the following lemma in the next section.

**Lemma 25.** If \( d_H (X, Y) < \epsilon/4 \) then
\[ F^i_\alpha (X, \epsilon) < 2^\alpha F^i_\alpha (Y, \epsilon/2) . \]

**Proof.** By stability, there is an injection
\[ \eta : PH^\epsilon_i (X) \rightarrow PH^{\epsilon/2}_i (Y) \]
so that for all \( I \in PH^\epsilon_i (X) \)
\[ |I| < |\eta (I)| + \epsilon/2 \leq 2 |\eta (I)| . \]

It follows that
\[ F^i_\alpha (X, \epsilon) = \sum_{I \in PH^\epsilon_i (X)} |I|^\alpha \]
\[ < \sum_{I \in PH^\epsilon_i (X)} 2^\alpha |\eta (I)|^\alpha \]
\[ \leq 2^\alpha \sum_{J \in PH^{\epsilon/2}_i (Y)} |J|^\alpha \]
\[ = 2^\alpha F^i_\alpha (Y, \epsilon/2) . \]
5. Upper Bounds

In this section, we prove the upper bounds for in Theorems 5 and 8, where the former assumes extremal hypotheses on the number of intervals of $PH_i(x_n)$ and the latter assumes that the expectation and variance of the number of intervals behave nicely.

In the extremal case, we closely follow the approach of Section 3.1. Instead of using that a minimum spanning tree on $n$ points has $n - 1$ edges, we assume that the number of intervals of $PH_i(x_n)$ is bounded above by $Dn^a$ for some constant $D$. We control $p_i(x_n, \delta)$ by approximating $x_n$ by with the centers of a maximal set of disjoint balls of radius $\delta/2$ and applying stability (Lemma 26). The asymptotics we found in the ball-counting lemma above (Lemma 14) then imply that $p_i(x_n, \delta) \leq C\delta^{-ad}$ for some constant $C > 0$ and all $x_n \subset X$. We convert this into a bound on $E_i^a(x_n)$ by integrating (using Lemma 20) and again using our assumption on the number of intervals, yielding the upper bound in Theorem 5 (Proposition 27).

While the extremal hypotheses allow us to prove the desired upper bound in Corollary 6, they are inadequate to show a similar upper bound for subsets of higher dimensional Euclidean space. Instead, we show that we can obtain a better upper bound on the scaling of $E_i^a(x_n)$ by assuming that

$$E(|PH_i(x_n)|) = O(n)$$

and

$$Var(|PH_i(x_n)|)/n^2 \to 0,$$

which are quantities that can be estimated in practice during the course of data analysis. We use Equation 6 to control the persistent homology of the support of the measure $(X)$ by approximating $X$ by a point sample in Lemma 29 and applying stability in Lemma 30, resulting in Proposition 31 on the asymptotics of truncated $\alpha$-weighted sums for $PH_i(X)$. With that, we write $PH_i(x_n)$ a sum of two terms, one which approximates $PH_i(X)$ and one which corresponds to “$d$-dimensional noise” at a certain scale. Controlling both terms gives a proof of the upper bound in Theorem 8 (Proposition 32).

5.1. Extremal Hypotheses. First, we prove the upper bound in Theorem 5, which implies the upper bound for our result on measures supported on a subset of $\mathbb{R}^2$ (Corollary 6). The next lemma uses bottleneck stability to convert an extremal bound on the number of persistent homology intervals of a set of $n$ points in a metric space $X$ into a bound on the number of intervals of length greater than $\epsilon$.
for any $Y \subseteq X$. It is the analogue of Lemma 19 for higher dimensional persistent homology.

**Lemma 26** (Interval Counting Lemma). *If $X$ is a bounded metric space so that*

$$|\text{PH}_i(x_1, \ldots, x_n)| < Dn^a.$$  

*for some positive real numbers $a$ and $D$ and all finite subsets $\{x_1, \ldots, x_n\}$ of $X$, then*

$$p_i(Y, \epsilon) < D'\epsilon^{-ad}$$  

*for some $D' > 0$, all $Y \subseteq X$, and all $\epsilon > 0$.*

**Proof.** Recall from Equation 5 that $p_i(Y, \epsilon)$ is the number of intervals of $\text{PH}_i(Y)$ of length greater than $\epsilon$.

Let $Y \subseteq X$, $\epsilon > 0$, and $\{y_j\}$ be the centers of a maximal set of disjoint balls of radius $\epsilon/4$ centered at points of $Y$. The balls of radius $\epsilon/2$ centered at the points $\{y_j\}$ cover $Y$ so

$$d_H(\{y_i\}, Y) < \epsilon/2$$

It follows that

$$p_i(Y, \epsilon) \leq p_i(\{y_i\}, 0) \quad \text{by stability}$$

$$\leq D |y_i|^a \quad \text{by hypothesis}$$

$$\leq DM_{\epsilon/4}(X)^a$$

$$\leq Dc^{a/4-a/d} \epsilon^{-ad} \quad \text{by Lemma 14}$$

as desired. □

The next proposition is the analogue of Proposition 21. The proof is nearly identical, and we do not repeat it here.

**Proposition 27.** *If $X$ satisfies the hypotheses of the previous lemma and $\alpha < ad$, then there exists a $D_\alpha > 0$ so that*

$$E^{i}_\alpha(x_1, \ldots, x_n) \leq D_\alpha n^{\frac{ad-\alpha}{d}}$$

*for all finite subsets $\{x_1, \ldots, x_n\} \subset X$ and all $n \in \mathbb{N}$. Furthermore there exists a $D_d > 0$ so that*

$$E^{i}_{ad}(x_1, \ldots, x_n) \leq D_d \log(n)$$

*for all finite subsets $\{x_1, \ldots, x_n\} \subset X$ and all $n \in \mathbb{N}$.*
We now prove the upper bound in Theorem 5.

Proof of the Upper Bound in Theorem 5. Let $\mu$ be a $d$-Ahlfors regular measure and let $X$ be the support of $\mu$. Assume that there are positive real numbers $D$ and $a$ so that 

$$|PH_i(x_n)| < Dn^a$$

for all finite subsets of $X$, an let $0 < \alpha < ad$.

By Lemma 14 there is a $c > 0$ so that 

$$M_\delta (X) \leq c \delta^{-d}$$

for all $\delta > 0$. Therefore, by the previous lemma there exists a $D_\alpha > 0$ so that 

$$E^0_\alpha (x_n) \leq D_\alpha n^{ad-\alpha}$$

for all collections of $n$ points $x_n \subset X$. □

5.2. Probabilistic Hypotheses. While the extremal hypotheses of the previous section allow us to prove the desired upper bound in Corollary 6, they are inadequate to show a similar upper bound for subsets of higher dimensional Euclidean space. Here, we show that hypotheses on the the expectation and variance of the number of $PH_i$ intervals of a set of $n$ points imply better asymptotic upper bounds (the upper bound in Theorem 8). The idea of the proof is to control the behavior of the support of the measure ($PH_i(X)$) in terms of the persistent homology of point samples from $X$. With that, we write $PH_i(x_n)$ a sum of two terms, one which approximates $PH_i(X)$ and one which corresponds to “$d$-dimensional noise” at a certain scale.

First, we require the following lemma, which follows from a standard argument using the union bound; see [54] for a proof.

Lemma 28. Let $\mu$ be a probability measure on a metric space $X$, and $\{B_j\}_{j=1}^l \subset X$ be a collection of balls so that so that $\mu (B_j) \geq a$ for all $j$. Then 

$$P (x_n \cap B_j \neq \emptyset \quad \text{for} \quad j = 1, \ldots, l) \geq 1 - le^{-an}.$$ 

Next, we apply the previous lemma to control the Hausdorff distance between $X$ and finite samples from an Ahlfors regular measure on $X$.

Lemma 29. If $\mu$ is a $d$-Ahlfors regular measure with support $X$ then there exists a positive real number $A_0$ depending only on the constants $c$ and $d$ appearing in the definition of Ahlfors regularity so that 

$$P (d_H (\{x_n\}, X) < \epsilon) \geq 1 - ce^{-d}e^{-A_0e^d n}$$

(7)
Proof. Let \( y = \{ y_1, \ldots, y_{M_{\epsilon/3}(X)} \} \) be the centers of a maximal set of disjoint balls of radius \( \epsilon/3 \) centered at points of \( X \). By the definition of Ahlfors regularity,

\[
\mu (B_{\epsilon/3} (y)) \geq A_0 \epsilon^d
\]

for all \( y \in y \), where \( A_0 = 3^{-d/c} \).

The balls of radius \( 2\epsilon/3 \) centered at the points of \( y \) cover \( X \) so

\[
d_H (y, X) < 2\epsilon/3.
\]

Therefore, if \( \{ x_n \} \cap B_{\epsilon/3} (y) \neq \emptyset \) for all \( y \in y \) then

\[
d_H (\{ x_n \}, X) < \epsilon/3 + 2\epsilon/3 = \epsilon.
\]

It follows that

\[
P (d_H (\{ x_n \}, X) < \epsilon) \geq P (\{ x_n \} \cap B_{\epsilon/3} (y) \neq \emptyset \text{ for all } y \in y)
\]

\[
\geq 1 - M_{\epsilon/3} (X) e^{-A_0 \epsilon^d}
\]

by Lemma 28

\[
\geq 1 - c \epsilon^{-d} e^{-A_0 \epsilon^d}
\]

by Lemma 14.

\[
\square
\]

In the next lemma, we show that if the expected number of persistent homology intervals of \( x_n \) is \( O(n) \), then we can control the number of “long” persistent homology intervals of \( X \) itself.

**Lemma 30.** Let \( X \) be a bounded metric space that admits a \( d \)-Ahlfors regular measure \( \mu \) satisfying

\[
\mathbb{E} (|PH_i (x_n)|) = O(n).
\]

Then there are positive real numbers \( A_1 \) and \( \epsilon_0 \) so that

\[
p_i (X, \epsilon) \leq A_1 \epsilon^{-d} \log (1/\epsilon)
\]

for all \( \epsilon < \epsilon_0 \).

**Proof.** By hypothesis, there are positive real numbers \( D_1 \) and \( N_1 \) so that

\[
\mathbb{E} (|PH_i (x_n)|) \leq nD_1/2
\]

for all \( n > N_1 \). By Markov’s inequality,

\[
P (|PH_i (x_n)| \leq nD_1) \geq 1/2.
\]
Manipulating the inequality in Equation 7 to solve for the number of points samples required to approximate $X$ within a distance of $\epsilon/2$ with probability exceeding $1/2$ gives that

\begin{equation}
\mathbb{P} \left( d_H \left( \{ x_1, \ldots, x_m(\epsilon) \} , X \right) < \epsilon/2 \right) \geq 1/2
\end{equation}

where

\begin{equation}
m(\epsilon) = \left\lceil \frac{2^d}{A_0} \epsilon^{-d} \log \left( 2^{d+1} c \epsilon^{-d} \right) \right\rceil.
\end{equation}

Note that $m(\epsilon)$ is chosen to give distances of less than $\epsilon/2$, rather than less than $\epsilon$. Let $\epsilon$ be sufficiently small so that $m(\epsilon) > N_1$. The events in Equations 8 and 9 both occur with probability greater than $1/2$ so there exists at least one point set in the intersection. That is, there exists a finite point set $x_1, \ldots, x_{m(\epsilon)}$ of $X$ so that

\begin{equation}
\left| PH_i \left( x_1, \ldots, x_{m(\epsilon)} \right) \right| \leq D_1 m(\epsilon)
\end{equation}

and

\begin{equation}
d_H \left( \{ x_1, \ldots, x_{m(\epsilon)} \} , X \right) < \epsilon.
\end{equation}

Therefore,

\[
p_i \left( X, \epsilon \right) \leq p_i \left( \{ x_1, \ldots, x_{m(\epsilon)} \} , 0 \right) \quad \text{by stability and Eqn. 12}
\leq \frac{D_1 m(\epsilon)}{m(\epsilon)} \quad \text{by Eqn. 11}
= \frac{D_1 \left[ \frac{2^d}{A_0} \epsilon^{-d} \log \left( 2^{d+1} c \epsilon^{-d} \right) \right]}{m(\epsilon)} \quad \text{by Eqn. 10}
= O \left( \epsilon^{-d} \log \left( 1/\epsilon \right) \right)
\]

as $\epsilon \to 0$. \hfill \square

Next, we use the previous lemma to control $F^i_\alpha(X, \epsilon)$, the truncated $\alpha$-weighted sum defined in Section 4.2:

\[
F^i_\alpha(X, \epsilon) = \sum_{I \in PH^c_i(X)} |I|^\alpha.
\]

where $PH^c_i(X)$ is the set of $PH_i$ intervals of $X$ of length greater than $\epsilon$.

**Proposition 31.** If $X$ satisfies the hypotheses of the previous lemma and $0 < \alpha < d$, then there exist positive real numbers $A_2$ and $\epsilon_1$ so that

\[
F^i_\alpha(X, \epsilon) \leq A_2 \epsilon^{\alpha-d} \log \left( 1/\epsilon \right)
\]

for all $\epsilon < \epsilon_1$. 

Proof. Without loss of generality, we may rescale $X$ so its diameter is less than one. By the previous lemma

\[ p_i (X, \epsilon) \leq f (\epsilon) := A_1 (\epsilon)^{-d} \log \left( \frac{1}{\epsilon} \right) \]

for all $\epsilon < \epsilon_0$. Applying Lemma 20 yields

\[ F^i_\alpha (Y, \epsilon) \leq \epsilon^\alpha f (\epsilon) + \alpha \int_{t=\epsilon}^{\epsilon_0} f (t) t^{\alpha-1} \, dt + F^i_\alpha (Y, \epsilon_0) \]  

By Equation 13, the first term of Equation 14 equals

\[ A_1 \epsilon^{\alpha-d} (\log (1/\epsilon)) \]

which has the desired asymptotics as $\epsilon \to 0$. The second term equals

\[ \alpha \int_{t=\epsilon}^{\epsilon_0} A_1 t^{\alpha-d-1} \log (1/t) \, dt = \]

\[ A_1 \left[ - \frac{1}{d-\alpha} t^{\alpha-d} \log (1/t) - \frac{1}{(d-\alpha)^2} t^{\alpha-d} \right]_{\epsilon}^{\epsilon_0} \]

\[ = A_1 \left( \frac{1}{d-\alpha} \epsilon^{\alpha-d} \log (1/\epsilon) + \frac{1}{(d-\alpha)^2} \epsilon^{\alpha-d} \right) \]

\[ = A_1 \left( \frac{1}{d-\alpha} \epsilon_0^{\alpha-d} \log (1/\epsilon_0) + \frac{1}{(d-\alpha)^2} \epsilon_0^{\alpha-d} \right) \]

\[ = O \left( \epsilon^{\alpha-d} \log (1/\epsilon) \right) \]

Therefore, $p_i (X, \epsilon) = O \left( \epsilon^{\alpha-d} \log (1/\epsilon) \right)$, as desired.

\[ \square \]

Finally, we can bootstrap the previous result to control $E^i_\alpha (x_n)$ and prove the upper bound in Theorem 8. For clarity, we restate that upper bound as a proposition.

**Proposition 32.** Let $\mu$ be a $d$-Ahlfors regular measure on a bounded metric space. If

\[ \mathbb{E} (|PH_i (x_n)|) = O (n) \]

and

\[ \text{Var} (|PH_i (x_n)|) / n^2 \to 0, \]

then there is a $\Lambda > 0$ so that

\[ E^i_\alpha (x_n) \leq \Lambda n^{d-\alpha} \log (n)^2 \]

with high probability as $n \to \infty$. 

Proof. Let
\begin{equation}
G^i_\alpha (x, \epsilon) = \sum_{I \in PH_i(x) \setminus PH^*_i(x)} |I|^\alpha.
\end{equation}

Our strategy is to write
\begin{equation}
E^i_\alpha (x_n) = G^i_\alpha (x_n, \epsilon) + F^i_\alpha (x_n, \epsilon)
\end{equation}
for a well-chosen $\epsilon$. The former term can be interpreted as “noise,” and the latter approximates the persistent homology of the support of $\mu$.

Let $0 < p < 1$, and let $D$ be a positive real number so that
\begin{equation}
\mathbb{E} (|PH_i(x_n)|) \leq (D/2) n
\end{equation}
for all sufficiently large $n$. By Chebyshev’s inequality,
\begin{equation}
\mathbb{P} (|PH_i(x_n)| > Dn) \leq \mathbb{P} \left( \frac{|PH_i(x_n)| - \mathbb{E} (|PH_i(x_n)|)}{\sqrt{\text{Var} (|PH_i(x_n)|)}} > Dn/2 \right) \leq \frac{4}{D^2n^2}
\end{equation}
which converges to 0 as $n \to \infty$, by hypothesis. Therefore, there is a $M$ so that
\begin{equation}
\mathbb{P} (|PH_i(x_n)| > Dn) < p/2
\end{equation}
for all $n > M$.

Solving for $\epsilon$ in Equation 7 gives that
\begin{equation}
\mathbb{P} (d_H (\{x_n\}, X) > \epsilon (n)/4) < p/2
\end{equation}
if
\begin{equation}
\epsilon (n) = 4A_0^{-1/d} n^{-1/d} W \left( \frac{2cA_0n}{p} \right)^{1/d},
\end{equation}
where $W$ is the Lambert W function. $W (m) \sim \log (m)$ as $m \to \infty$, and $W (m) \leq \log (m)$ for $m \geq e$ [40]. Therefore, there are positive real numbers $A_3$ and $N_1 (p)$, where the former does not depend on $p$ but the latter does, so that
\begin{equation}
\frac{A_3}{2} n^{-1/d} \log (n)^{1/d} \leq \epsilon (n) \leq A_3 n^{-1/d} \log (n)^{1/d}
\end{equation}
for all $n > N_1 (p)$.

The right hand side goes to zero as $n \to \infty$ so we can choose $N_2 (p) > N_1 (p)$ to be sufficiently large so that $\epsilon (n) < \epsilon_1$ for all $n > N_2 (p)$, where $\epsilon_1$ is given in Proposition 31. Let $n > N_2 (p)$. 

and suppose that $x_n$ satisfies
\begin{equation}
|PH_i(x_n)| < Dn \quad \text{and} \quad d_H(x_n, X) < \epsilon(n)/4,
\end{equation}
an event which occurs with probability greater than $1 - p$ by Equations 16 and 17.

Write
\begin{equation}
E^i_\alpha(x_n) = F^i_\alpha(x_n, \epsilon(n)) + G^i_\alpha(x_n, \epsilon(n)).
\end{equation}

We consider the two terms separately.

\begin{align*}
G^i_\alpha(x_n, \epsilon(n)) &\leq D|x_n|\epsilon(n)\alpha \\
&\leq 2^nD\alpha A_3 n^{d-\alpha} \log(n)^{\alpha/d} \\
&= A_4 n^{d-\alpha} \log(n)^{\alpha/d},
\end{align*}

where $A_4 = 2^nDA_3^\alpha$ is a positive constant that does not depend on $n$ or $p$.

To bound the second term in Equation 20, we apply Lemma 25 to find
\begin{align*}
F^i_\alpha(x, \epsilon(n)) &\leq 2^nF^i_\alpha(X, \epsilon(n)/2) \\
&\leq A_2(\epsilon(n))^{\alpha-d} \log\left(\frac{1}{\epsilon(n)}\right) \\
&\leq A_2A_3^{\alpha-d} n^{d-\alpha} \log(n)^{d-\alpha} \log\left(\frac{1}{2A_3 n^{1/d} \log(n)^{-1/d}}\right) \\
&= A_2A_3^{\alpha-d} n^{d-\alpha} \log(n)^{d-\alpha} \left(\frac{1}{d} \log(n) - \log\left(2A_3 \log(n)^{1/d}\right)\right) \\
&\leq \frac{1}{d} A_2A_3^{\alpha-d} n^{d-\alpha} \log(n)^{\alpha/d} \\
&= A_5 n^{d-\alpha} \log(n)^{\alpha/d},
\end{align*}

where $A_5 = \frac{1}{d} A_2A_3^{\alpha-d}$ is a positive constant that does not depend on $n$ or $p$.

In summary, if $\Lambda = A_4 + A_5$ and $0 < p < 1$, then there exists an $N_2(p) > 0$ so that
\begin{equation}
\mathbb{P}\left(E^i_\alpha(x_n) \leq \Lambda n^{d-\alpha} \log(n)^{\alpha/d}\right) > 1 - p
\end{equation}
for all $n > N_2(p)$.
6. The Lower Bound

In this section, we prove the lower bound in Theorems 5 and 8. While our proofs of the upper bounds work for Ahlfors regular measures on arbitrary bounded metric spaces, here we restrict our attention to Ahlfors regular measures on Euclidean space. This will allow us to use the structure of the cubical grid on $\mathbb{R}^m$.

We remind the reader of the occupancy indicators defined in Section 2.3. If $x$ is a point set, $A$ is a set, and $B$ is a collection of sets then

$$\Xi(x, A, B) = \begin{cases} 1 & \delta(A, x) = 0 \quad \text{and} \quad \delta(B, x) = 1 \quad \forall B \in B, \\ 0 & \text{otherwise} \end{cases}$$

where for any set $C$

$$\delta(C, x) = \begin{cases} 0 & C \cap x = \emptyset, \\ 1 & C \cap x \neq \emptyset. \end{cases}$$

To prove the lower bound, we modify the approach in our paper on extremal $PH$-dimension [60] to work in a probabilistic context. The outline of the argument is similar to that in Section 3.2, but more care is required to construct occupancy indicators implying the existence of persistent homology intervals. We work on two different length-scales: we divide the ambient Euclidean space into cubes of width $n^{-1/d}$, and divide each of these cubes into $k^m$ sub-cubes of width $n^{-1/d}/k$. Using the non-triviality constants defined in [60] (Definition 35), we show that if a cube contains sufficiently many sub-cubes that overlap with the support of the measure, then we can define an occupancy indicator guaranteeing the existence of a certain $PH_i$ interval. We count the number of cubes with sufficiently many occupied sub-cubes in Lemma 39, and apply Lemma 17 to the corresponding occupancy indicators to give

$$p_i(x, \epsilon_0 n^{-1/d}) \geq \Omega_1 n$$

with high probability as $n \to \infty$ for some $\Omega_1 > 0$ (Lemma 40). Summing over intervals of length greater than $\epsilon_0 n^{-1/d}$ proves the desired lower bound (Proposition 41).

The proof is complicated, so we warm up with the special case of an $m$-Ahlfors regular measure on $\mathbb{R}^m$. The approach is more straightforward, but contains some of the same elements. These arguments also appear in our unpublished manuscript [59], which has largely been subsumed into the current work. First, we find an occupancy indicator defined in terms of sub-cubes of a larger cube that guarantees the existence
FRACTAL DIMENSION AND PERSISTENT HOMOLOGY

of a persistent homology interval of a given length, regardless of what happens outside of the cube in Lemma 34. Then, we assemble a collection of these occupancy indicators to show the lower bound in Proposition 33.

6.1. The Absolutely Continuous Case. Note that if \( \mu \) is an \( m \)-Ahlfors regular measure on \( \mathbb{R}^m \), then \( \mu \) is comparable to the Lebesgue measure on its support and is thus absolutely continuous with respect to it.

**Proposition 33.** Let \( \mu \) be an \( m \)-Ahlfors regular measure on \( \mathbb{R}^m \). There exist a constant \( \Psi > 0 \) so that

\[
\lim_{n \to \infty} n^{-\frac{d-\alpha}{\alpha}} F^i_\alpha(x_1, \ldots, x_n) \geq \Psi
\]

with high probability.

Before proving the proposition, we state and prove a preliminary lemma to find an occupancy indicator guaranteeing the existence of a persistent homology interval of a given length, regardless of what happens outside of the cube (in a sense made precise in Equation 21 below). The idea is to take \( \mathcal{B} \) to be the set of sub-cubes that intersect an \( i \)-dimensional sphere sphere that is separated from the boundary of a cube, as shown in Figure 4. Let

\[
J_{\epsilon,i}(X) = \{(b,d) \in \text{PH}_i(X) : d \leq \epsilon \}.
\]

**Lemma 34.** Let \( 0 \leq i < m \), and \( 0 < b < d < 1/8 \). There exists a \( \lambda_0 > 0 \) so that if \( C \subset \mathbb{R}^m \) is an \( m \)-dimensional cube of width \( R \) and \( \lambda > \lambda_0 \), there exists a collection \( \mathcal{B} \) of disjoint, congruent cubes of width \( R \lambda - \frac{R}{m} \) so that if \( A = C \setminus \bigcup_{B \in \mathcal{B}} B \) and \( \Xi(x,A,\mathcal{B}) = 1 \) then \( \text{PH}_i(x \cap C) \) contains an interval \((\hat{b}, \hat{d})\) with

\[
0 < \hat{b} < Rb < Rd < \hat{d}.
\]

Furthermore,

\[
J_{\hat{d},i}(x) = J_{\hat{d},i}(x \cap C) \cup J_{\hat{d},i}(x \setminus (x \cap C)) .
\]

**Proof.** We may assume without loss of generality that \( R = 1 \) and \( C \) is centered at the origin. Let \( S^i \subset \mathbb{R}^m \) be an \( i \)-dimensional sphere of diameter \( 1/4 \) centered at the origin; note that \( \text{PH}_i(S^i) \) consists of a single interval \((0, 1/8)\) for the Čech complex (a slightly different argument is required for the Rips complex).

Let

\[
\kappa = \min \left( b, \frac{1}{8} - d, \frac{1}{24} \right)
\]
and

$$\lambda_0 = \frac{m^{m/2}}{\kappa^m}.$$  

Choose $\lambda > \lambda_0$ and set $\delta = \lambda^{-\frac{1}{m}}$. Let $C$ be the cubes in the standard tesselation of $\mathbb{R}^m$ by cubes of width $\delta$ and let

$$B = \{ c \in C : S_i \cap c \neq \emptyset \}.$$  

See Figure 4.

If $\Xi(x, A, B) = 1$, then

$$d_H(x \cap C, S_i) < \kappa$$  

where we used the fact that the length of the diagonal of an $m$-dimensional cube of width $\delta$ is $\delta \sqrt{m}$. Stability and Equation 22 imply that $PH_i(x \cap C)$ includes an interval $(\hat{b}, \hat{d})$ so that

$$\hat{b} < \kappa \leq b < d < \frac{1}{8} - \kappa < \hat{d} < \frac{1}{8} + \kappa \leq 1/6.$$  

By construction,

$$\frac{1}{2} d(x \cap C, C^c) > \frac{1}{2} \left( d(S_i, C^c) - \kappa \right) = \frac{3}{16} - \frac{\kappa}{2} \geq 1/6 > \hat{d},$$  

where $C^c$ is the complement of $C$. Therefore, the $\epsilon$-neighborhoods of $x \cap C'$ and $C^c$ are disjoint for all $\epsilon \leq \hat{d}$ and Equation 21 holds. \hfill \Box

**Proof of Proposition 33.** We will construct a set of bounded occupancy indicators of the form defined in the previous lemma, and apply Lemma 17. The reader may want to remind themselves of the definitions in Section 2.3.

$\mu$ is absolutely continuous so its support contains a cube $C$. Without loss of generality, we may assume that $C$ is a unit cube. Let $b_0 = 1/16, d_0 = 1/8$, and $\lambda > \lambda_0$, where $\lambda_0$
is as in the previous lemma. Set $\delta = n^{-1/m}$, and let $\{D_1, \ldots, D_s\}$ be the sub-cubes in the cubical tessellation of width $\delta$ which are fully contained within $C$. There is a constant $\kappa > 0$ depending only on $m$ so that

$$s \geq \kappa \delta^{-m} \geq \kappa n. \quad (23)$$

Assume $\delta$ is sufficiently small so that $k > \delta^m/2$. Let $l \in \{1, \ldots, s\}$, and let $A_l$ and $B_l$ be the set and collection of disjoint sub-cubes of width $\delta \lambda^{-\frac{1}{m}}$ contained in $C_l$ given by the previous lemma. It follows from the statement of that lemma that

$$p_i \left( x_n, \frac{1}{16} n^{-1/m} \right) \geq \sum_{j=1}^{s} \Xi (x_n, A_l, B_l). \quad (24)$$

Let $c$ be the constant appearing the definition of Ahlfors regularity, $v_0$ be the volume of a unit ball in $\mathbb{R}^m$, and

$$q = \frac{cm^{m/2}v_0}{2^m} \quad \text{and} \quad p = \frac{v_0}{\lambda^2mc}.$$  

If $E_0$ is a ball of radius $\delta \sqrt{m}/2$ containing $C$,

$$\mu (A_l) \leq \mu (E_0) \leq c \text{vol} (E_0) = cv_0 \left( \delta \sqrt{m}/2 \right)^m = q \delta^m = \frac{q}{n}.$$  

Similarly, if $B$ is a cube of $B_l$, and $E_1$ is a ball of radius $\delta \lambda^{-\frac{1}{m}}/2$ contained in $B$

$$\mu (B) \geq \mu (E_1) \geq \frac{1}{c} \left( \delta \lambda^{-\frac{1}{m}} \right)^m v_0 = \frac{p}{n}.$$  

Let $r = |B_l|$ and note that $r$ depends only on $\lambda_0, b_0, \text{ and } d_0$. $\Xi (x_n, A_l, B_l)$ is a $n, p, q, r$-bounded occupancy indicator for each $l$, so by Lemma 17 there exists a $\gamma_0 > 0$ so that

$$\frac{1}{s} \sum_{j=1}^{s} \Xi (x_n, A_l, B_l) \geq \gamma_0 \quad (25)$$

with high probability as $n \to \infty$. We have that

$$p_i \left( x_n, \frac{1}{16} n^{-1/m} \right) \geq \sum_{j=1}^{s} \Xi (x_n, A_l, B_l) \quad \text{by Eqn. 24}$$

$$\geq \gamma_0 s \quad \text{by Eqn. 25}$$

$$\geq \gamma_0 \kappa n \quad \text{by Eqn. 23}$$

with high probability as $n \to \infty$.  

Then, by counting intervals of length greater than \( n^{-1/m}/16 \),
\[
\lim_{n \to \infty} n^{-\frac{m-\alpha}{m}} E^i_{\alpha} (x_n) \geq \lim_{n \to \infty} n^{-\frac{m-\alpha}{m}} p_i \left( x_n, \frac{1}{16} n^{-1/m} \right) \left( \frac{1}{16} (n^{-1/d}) \right)^\alpha 
\]
\[
= 16^{-\alpha} \lim_{n \to \infty} \frac{1}{n} p_i \left( x_n, \frac{1}{16} n^{-1/d} \right) 
\]
\[
\geq 16^{-\alpha} \kappa_0 
\]
\[
:= \Omega_0 
\]
with high probability as \( n \to \infty \). \( \square \)

It is straightforward to modify the previous argument to work for any metric space \( X \) with a subset \( Y \) that is the bi-Lipschitz image of a cube in Euclidean space. In particular, if the bi-Lipschitz constant is \( L \), it would suffice to take \( b_0 \) to be \( \frac{1}{16L^2} \) and \( d_0 \) to be \( \frac{1}{8} \) and argue that an interval \((b,d) \in PH_i(C)\) with \( b < \frac{\delta}{16L^2} < \frac{\delta}{8} \) corresponds to an interval \((b_1,d_1) \in PH_i(X)\) with \( b_1 < \frac{\delta}{16L} < \frac{\delta}{8L} < d_1 \).

### 6.2. Non-triviality Constants

To prove the lower bound, we modify the approach in our paper on extremal \( PH \)-dimension [60] to work in a probabilistic context. If \( \mu \) is a \( d \)-Ahlfors regular measure on \( \mathbb{R}^m \) and \( \delta > 0 \), let \( C_\delta (\mu) \) be the cubes in the grid of mesh \( \delta \) that intersect the support of \( \mu \). The basic idea is to sub-divide the grid of mesh \( \delta \) so each cube contains \( k^m \) sub-cubes. If \( k \) is chosen carefully, we can find a positive fraction of cubes in \( C_\delta (\mu) \) that contain enough cubes of \( C_{\delta/k} (\mu) \) to guarantee a stable \( PH_i \) class. In fact, we can require that the sub-cubes have probability exceeding a certain threshold. We then control the number of stable \( PH_i \) classes realized by a random sample \( x_n \) with Lemma 17.

In previous work [60], we raised the question of how large a subset of the integer lattice can be without having a subset with “stable” \( i \)-dimensional persistent homology.

**Definition 35.** For \( x \in \mathbb{Z}^m \), let the cube corresponding to \( x - C(x) \) — be the cube of width 1 centered at \( x \). A subset \( X \) of \( \mathbb{Z}^m \) has a **stable** \( i \)-dimensional persistent homology class if there is a \( c > 0 \) so that if \( Y \) is any subset of \( \bigcup_{x \in X} C(x) \) satisfying
\[
Y \cap C(x) \neq \emptyset \quad \forall \ x \in X, 
\]
then there is an \( I \in PH_i(Y) \) so that \(|I| > c\) (see Figure 5). The supremal such \( c \) is called the **size** of the stable persistence class.

Note that this notion depends on whether persistent homology is taken with respect to the Rips complex or the Čech complex, but is defined for both.
Figure 5. The Čech $PH_1$ class of the lattice points corresponding to the gray cubes in (a) and (b) is stable — any choice of one point in each cube will give the vertices of an acute triangle, and therefore a set with non-trivial $PH_1$. The one in (c) and (d) is not, because the points in (d) form an obtuse triangle so the persistent homology of that set is trivial. [60]

Definition 36. Let $\xi_i^m(N)$ be the size of the largest subset $X$ of $\{1, \ldots, N\}^m \subset \mathbb{Z}^m$ so that no subset $Y$ of $X$ has a stable $PH_i$-class. Define

$$\gamma_i^m = \liminf_{N \to \infty} \frac{\log(\xi_i^m(N))}{\log(N)}.$$ 

$\gamma_i^m$ may depend on whether persistent homology is taken with respect to the Rips complex or the Čech complex, but we suppress the dependence here. $\gamma_0^m = 0$ for all $m \in \mathbb{N}$: any subset of $\mathbb{Z}^m$ with more than $3^m$ points has a minimum spanning tree edge of length at least 1 and thus a $PH_0$ interval of at length at least 1/2 for the Čech complex and one of length at least 1 for the Rips complex (at least $3^m$ points are necessary to rule out point sets with points from neighboring cubes). In [60], we proved that $\gamma_1^m \leq m - \frac{1}{2}$ if persistent homology is taken with respect to the Čech complex. Note that Definition 36 does not include the same restriction on the size as in [60].

6.3. Ahlfors Regular Measures and Box Counting. Before proceeding to the proof of the lower bound, we prove two technical lemmas about the asymptotics of the number of cubes that intersect the support of a $d$-Ahlfors regular measure. The first is similar to Lemma 14 on the asymptotic number of disjoint balls. Let $C_\delta$ be the cubes in the cubical grid of mesh $\delta$ in $\mathbb{R}^m$ centered at the origin, and for $\delta, a > 0$ define

$$(26) \quad C_{\delta,a}(\mu) = \{ C \in C_\delta : \mu(C) \geq a\delta^d \}$$

and

$$(27) \quad N_{\delta,a}(\mu) = |C_{\delta,a}(\mu)|.$$
(The upper and lower box dimensions of a subset of Euclidean space can be defined in terms of the asymptotic properties of $N_{\delta,0}(X)$, analogously to Definition 13.)

**Lemma 37.** If $\mu$ is a $d$-Ahlfors regular measure with support $X \subset \mathbb{R}^m$, then there exist real numbers $0 < c_0 \leq c_1 < \infty$ depending on $m$ and the constants $c$ and $d$ appearing in the definitions of Ahlfors regularity so that

$$c_0 \delta^{-d} \leq N_{\delta,\hat{c}}(\mu) \leq c_1 \delta^{-d}$$

for all $\delta < \delta_0$, where $\hat{c} = \frac{1}{c^2m}$. Similarly, there exist real numbers $0 < c'_0 \leq c'_1 < \infty$ depending on $c$, $d$, and $m$ so that

$$c'_0 \delta^{-d} \leq N_{\delta,0}(\mu) \leq c'_1 \delta^{-d}$$

for all $\delta < \delta_0$.

**Proof.** Let $C$ be a cube in the grid of mesh $\delta$ that intersects $X$, and $x \in C \cap X$. First, we show that bounds for $N_{\delta,0}(\mu)$ imply bounds for $N_{\delta,\hat{c}}(\mu)$, and vice versa. By Ahlfors regularity,

$$\mu(B_\delta(x)) > \frac{1}{c} \delta^d.$$  

Also, $B_\delta(x)$ intersects at most $2^m$ cubes in the grid of mesh $\delta$, so at least one cube adjacent to $C$ has measure exceeding $\hat{c} \delta^d$ (where two cubes are adjacent if they share at least one point). Each cube of $C_{\delta,\hat{c}}(\mu)$ is adjacent to at most $3^m$ cubes of $C_{\delta}(\mu)$, so we can find a lower bound for $N_{\delta,\hat{c}}(\mu)$ in terms of the number of cubes that intersect the support:

$$\frac{1}{3^m} N_{\delta,0}(\mu) \leq N_{\delta,\hat{c}}(\mu) \leq N_{\delta,0}(\mu),$$

where the upper bound is trivial.

To show the lower bounds in the statement, we compute

$$1 = \mu(X) \leq \sum_{C \in C_{\delta,0}(\mu)} \mu(C) \leq c \delta^d m^{d/2} N_{\delta,0}(\mu) \implies N_{\delta,0}(\mu) \geq \frac{1}{c} m^{d/2} \delta^{-d}$$

which is the lower bound in Equation 29 with $c'_0 = \frac{1}{c} m^{d/2}$. Then, by Equation 30, the lower bound in Equation 28 holds with $c'_0 = 3^{-m} \frac{1}{c} m^{d/2}$. 

For the upper bounds, note that the intersection of two cubes may have positive measure, but a cube can share measure with only $3^m - 1$ adjacent cubes. It follows that

$$1 = \mu(X) \geq \frac{1}{3^m} \hat{c} \delta^d N_{\delta, \hat{c}}(\mu) \implies N_{\delta, \hat{c}}(\mu) \leq c 6^m \delta^{-d},$$

which is the upper bound in Equation 28 with $c_1 = c 6^m$. Then, upper bound in Equation 29 holds with $c'_1 = c_1 = c 18^m$, using Equation 30.

We consider cubes at two different scales: cubes of width $\delta$, and smaller cubes obtained by dividing each cube of width $\delta$ into $k^m$ sub-cubes. Our eventual goal is to count the number of cubes of width $\delta$ which contain sufficiently many positive measure sub-cubes of width $\delta/k$ to define an occupancy event implying a persistent homology class. The next definition introduces collections of cubes corresponding to a measure $\mu$, some of which are illustrated in Figure 6.

**Definition 38 (Cube Collections Corresponding to a Measure).** Let $\mu$ be a $d$-Ahlfors regular measure on $\mathbb{R}^m$ and let $\mathcal{C}_{\delta, \alpha}(\mu)$ be as defined in Equation 26. For $k \in \mathbb{N}$, $\delta > 0$, and $C \in \mathcal{C}_{\delta, 0}(\mu)$, define

$$\mathcal{D}_k(C) = \{ D \in \mathcal{C}_{\delta/k, \hat{c}}(\mu) : D \subset C \}$$

where $\hat{c} = \frac{1}{c 2^m}$ as in Lemma 37 above, and set

$$D_k(C) = |\mathcal{D}_k(C)|.$$

Next, we define a collection of cubes in $\mathcal{C}_{\delta, 0}(\mu)$ which contain sufficiently many sub-cubes. For $\delta > 0$ and $0 < \beta < d$, let

$$\mathcal{C}^{k, \beta}_{\delta} = \{ C \in \mathcal{C}_{\delta, 0}(\mu) : D_k(C) > k^\beta \}$$
and
\[ M (\delta, k, \beta) = \left| \mathcal{C}_\delta^{k,\beta} \right|. \]

Next, we prove a technical lemma establishing a lower bound for \( M (\delta, k, \beta) \). The argument is similar to that of Lemma 26 in [60].

**Lemma 39.** If \( \mu \) is a \( d \)-Ahlfors regular measure supported on \( \mathbb{R}^m \) and \( 0 < \beta < d \), then there exists a \( K \) so that for any \( k > K \) there exit positive constants \( \delta_1 \) and \( c_2 \) so that
\[
M (\delta, k, \beta) > c_2 \delta^{-d}
\]
for all \( \delta < \delta_1 \).

**Proof.** Let \( c_0, c_1, \) and \( \delta_0 \) be the constants from Lemma 37 so
\[
N_{\delta,0} (\mu) \leq c_1 \delta^{-d} \quad \text{and} \quad N_{\delta,\hat{c}} (\mu) \geq c_0 \delta^{-d}
\]
for all \( \delta < \delta_0 \).

A cube in \( C_{\delta,0} (\mu) \) is either an element of \( \mathcal{C}_\delta^{k,\beta} \) and contains between \( k^\beta \) and \( k^m \) sub-cubes of \( C_{\delta/k,\hat{c}} (\mu) \), or is contained in \( C_{\delta,0} (\mu) \setminus \mathcal{C}_\delta^{k,\beta} \) and can contain at most \( k^\beta \) sub-cubes in that set. On the other hand, each sub-cube in \( C_{\delta/k,\hat{c}} (\mu) \) is contained in exactly one larger cube in \( C_{\delta,0} (\mu) \). Therefore,
\[
N_{\delta/k,\hat{c}} (\mu) \leq k^m M (\delta, k, \beta) + k^\beta \left| C_{\delta,0} (\mu) \setminus \mathcal{C}_\delta^{k,\beta} \right|
\leq k^m M (\delta, k, \beta) + k^\beta N_{\delta,0} (\mu).
\]

Re-arranging terms, we have that
\[
M (\delta, k, \beta) \geq \frac{N_{\delta/k,\hat{c}} (\mu) - k^\beta N_{\delta,0} (\mu)}{k^m}
\geq \frac{c_0 k^d \delta^{-d} - k^\beta c_1 \delta^{-d}}{k^m}
\geq \left( c_0 k^{d-m} - c_1 k^{\beta-m} \right) \delta^{-d}.
\]

As \( \beta < d \), we can choose \( K \) sufficiently large so that if \( k > K \) then the coefficient
\[
c_2 := \left( c_0 k^{d-m} - c_1 k^{\beta-m} \right),
\]
is positive, and Equation 32 holds for all \( \delta < \delta_0 \), as desired. \( \square \)
6.4. Proof of the Lower Bound in Theorems 5 and 8. We require one more lemma before proving the lower bound. The idea is similar to that of Lemma 23: we assemble a collection of occupancy indicators which each imply the existence of a persistence interval of a given length using Definition 36 and Lemma 39, and apply Lemma 17 to bound the total number of intervals in probability.

Lemma 40. If \( \mu \) be a \( d \)-Ahlfors regular measure on \( \mathbb{R}^m \) with \( d > \gamma_i^m \), then there exist positive real numbers \( \epsilon_0 \) and \( \Omega_1 \) so that

\[
\lim_{n \to \infty} \frac{1}{n} p_i (x_n, \epsilon_0 n^{-1/d}) \geq \Omega_1
\]

with high probability.

Proof. Let \( \gamma_i^m < \beta < d \). By Definition 36, we can find a \( K_0 \) so that \( k^\beta > \xi_i^m (k) \) for all \( k > K_0 \). Let \( k > \min(K, K_0) \), where \( K_0 \) is as given in the previous lemma, and let \( \delta_1 \) and \( c_2 \) also be as in that lemma. There are only finitely many collections of sub-cubes of \( [k]^m \), so there are only finitely many stable \( PH_i \) classes of subsets of \( [k]^m \). Let \( \epsilon_0 \) be the minimum of the sizes of these stable classes.

Let \( \delta = n^{-1/d} \) and choose \( n \) large enough so that \( \delta < \delta_1 \). We will define a collection of occupancy indicators in terms of subsets of cubes in \( C_{\delta}^{k,\beta} \) which imply the length of a \( PH_i \) interval of length at least \( \epsilon_0 \). To ensure that the indicators do not interfere with each other, let \( \{D_1, \ldots, D_s\} \) be a maximal collection of cubes in \( C_{\delta}^{k,\beta} \) so that

\[
d (D_j, D_l) > (\delta + 1) \sqrt{m}
\]

for all \( j, l \in \{1, \ldots, s\} \) so that \( j \neq l \). See Figure 7. There is a constant \( 0 < \kappa < 1 \) that depends only on \( d \) so that \( s \geq \kappa M (\delta, k, \beta) \). Furthermore, by the previous lemma,

\[
s \geq \kappa M (\delta, k, \beta) > \kappa c_2 \delta^{-d} = \kappa c_2 n .
\]

Let \( l \in \{1, \ldots, s\} \). By construction, \( D_k (D_l) \) (defined in Equation 31) contains at least \( k^\beta \) sub-cubes. \( k > K_0 \), so \( k^\beta > \xi_i^m (k) \) and there is a collection of sub-cubes \( B_l \subset D_k (D_l) \) with a stable \( PH_i \) class (using Definition 36). Let

\[
A_l = \hat{B}_{\delta \sqrt{m}} (C) \setminus \bigcup_{B \in B_l} B
\]

where \( \hat{B}_{\delta \sqrt{m}} (D_l) \) is the union of all cubes in the grid of mesh \( \delta/k \) within distance \( \delta \sqrt{m} \) of \( D_l \) (see Figure 7). Also, let \( B'_l \) be collection of the interiors of the sub-cubes \( B_l \). Note that Equation 34 implies that the sets \( A_l \) and \( B'_l \) are disjoint for different values of \( l \). It follows from property (2) in Section 4.1 that

\[
p_i (x_n, \epsilon_0 n^{-1/d}) \geq \sum_{j=1}^{s} \Xi (x_n, A_l, B'_l) .
\]
A_l is contained in a ball of radius $\delta\sqrt{m} + \delta$ so if $q = c(\sqrt{m} + 1)^d$ then, by Ahlfors regularity,

$$\mu(A_l) \leq c\delta^d \sqrt{m} + 1^d = \frac{q}{n}$$

for all $l \in \{1, \ldots, s\}$. Also, each $B \in B_l$ is a cube of width $\delta/k$ in $\mathbb{R}^m$ so

$$\mu(B) \geq \frac{1}{c}\left(\frac{\delta\sqrt{m}}{2k}\right)^d = \frac{p}{n},$$

where $p = 2^{-d}k^{-d}m^{d/2}/c$. Therefore, $\Xi(x_n, A_l, B_l)$ is a $n, p, q, k^m$-bounded occupancy indicator for each $l$, and the desired result follows from Lemma 17. \hfill \Box

The proof of the lower bound in Theorems 5 and 8 is now straightforward.

**Proposition 41.** Let $\mu$ be a $d$-Ahlfors regular measure on $\mathbb{R}^m$ with $d > \gamma_i^m$. Then there is an $\Omega > 0$ so that

$$\lim_{n \to \infty} n^{-\frac{d-\alpha}{d}} E_{\alpha}^i (x_1, \ldots, x_n) \geq \Omega$$

with high probability.
Proof. Let \( \epsilon_0 \) be as in the previous lemma. By counting intervals of length greater than \( \epsilon_0 n^{-1/d} \), we have that
\[
\lim_{n \to \infty} n^{-d/a} E^{\alpha}_i(x_n) \geq \lim_{n \to \infty} n^{-d/a} p_i \left( x_n, \epsilon_0 n^{-1/d} \right) \left( \epsilon_0 n^{-1/d} \right)^{\alpha} = \epsilon_0^\alpha \lim_{n \to \infty} \frac{1}{n} p_i \left( x_n, \epsilon_0 n^{-1/d} \right) \geq \epsilon_0^\alpha \Omega_1 \quad \text{by Lemma 40}
\]
with high probability as \( n \to \infty \). \( \Box \)

7. Acknowledgments

We would like to thank H. Adams and M. Kahle for interesting discussions. In particular, the computational experiments of Adams et al. [2] helped to inspire this work. We would also like to thank J. Jaquette and M. Kahle for their helpful comments. Moreover, we are grateful to the anonymous referee for their valuable comments, which have led to an improved manuscript.

Funding for this research was provided by a NSF Mathematical Sciences Postdoctoral Research Fellowship under award number DMS-1606259.

References

We will construct a $d$-Ahlfors regular measure $\sigma$ with $d = \frac{\log(2)}{\log(3)}$ so that if $\{z_j\}_{j \in \mathbb{N}}$ are i.i.d. samples from $\mu$ and $0 < \alpha < d$ then the quantity

$$n^{-\frac{d-\alpha}{d}} \mathbb{E}_0(\alpha) (z_1, \ldots, z_n)$$

oscillates with high probability as $n \to \infty$. Our example will be constructed as the intersection of a nested sequence of closed subsets $Y_1 \supset Y_2 \supset Y_3 \ldots$ of $[0, 1]$, where each $Y_j$ is the union of finitely many congruent, disjoint intervals. At some scales the set will resemble the Cantor set, while at others it will resemble the Cantor set scaled by a factor $\frac{5}{7}$. As described at the end of this section, the construction can easily be modified to produce a counterexample of dimension $d$ for any $d \in (0, 1)$.

We introduce notation and shorthand related to sets of intervals. Call a finite set of disjoint intervals $\mathcal{I}$ an “interval collection.” We will abuse notation, and use $\mathcal{I}$ to refer to both the collection $\mathcal{I}$ and the union $\bigcup_{I \in \mathcal{I}} I$. Let $|\mathcal{I}|$ be the number of intervals in the collection, and $\|\mathcal{I}\|$ be the minimum length of an interval.
Before proving Counterexample 4, we prove three technical lemmas. The first one shows that if two point sets have the same “interval membership” in a fine enough interval collection, then the length of the corresponding minimum spanning trees is close. If \( \mathcal{I} = \{ I_j \}_{j=1}^k \) and \( \{ x_1, \ldots, x_n \} \subset \mathcal{I} \) let \( \phi_{\mathcal{I}}(x_1, \ldots, x_n) \) record the interval membership of the points \( x_1, \ldots, x_n \):

\[
\phi_{\mathcal{I}}(x_1, \ldots, x_n) = (l_1, \ldots, l_n) \text{ if } x_1 \in I_{l_1}, \ldots, x_n \in I_{l_n}.
\]

**Lemma 42.** Let \( n \in \mathbb{N}, \epsilon_0 > 0, \) and \( \alpha > 0. \) There exists a \( \delta > 0 \) so that if \( \mathcal{I} \) is an interval collection with \( \|\mathcal{I}\| < \delta \) and \( \{ x_1, \ldots, x_n \}, \{ y_1, \ldots, y_n \} \subset \mathcal{I} \) satisfy

\[
\phi_{\mathcal{I}}(x_1, \ldots, x_n) = \phi_{\mathcal{I}}(y_1, \ldots, y_n)
\]

then

\[
| E_0^0(x_1, \ldots, x_n) - E_0^0(y_1, \ldots, y_n) | < \epsilon_0.
\]

**Proof.** The function \( x \to x^\alpha \) is \( \alpha \)-Holder continuous on \([0,1] \) so there exists a \( C > 0 \) so that

\[
|x^\alpha - y^\alpha| < C |x - y|^\alpha
\]

for all \( x, y \in [0,1] \). Let

\[
\delta = \frac{1}{2} \left( \frac{\epsilon_0}{Cn} \right)^{1/\alpha}.
\]

If \( \mathcal{I}, \{ x_1, \ldots, x_n \} , \) and \( \{ y_1, \ldots, y_n \} \) satisfy the hypotheses then \( |x_i - y_i| < \delta \) for \( i = 1, \ldots, n, \) because \( x_i \) and \( y_i \) are contained in an interval whose length is less than \( \delta. \)

It follows that

\[
| E_0^0(x_1, \ldots, x_n) - E_0^0(y_1, \ldots, y_n) | = \sum_{i=1}^{n-1} (x_{i+1} - x_i)^\alpha - (y_{i+1} - y_i)^\alpha
\]

\[
\leq \sum_{i=1}^{n-1} (x_{i+1} - x_i)^\alpha - (y_{i+1} - y_i)^\alpha
\]

\[
\leq \sum_{i=1}^{n} C |(x_{i+1} - y_{i+1}) + (x_i - y_i)|^\alpha \text{ by Eqn. } 35
\]

\[
< nC2^\alpha \delta^\alpha \text{ by } \|\mathcal{I}\| < \delta
\]

\[
= \epsilon_0 \text{ by Eqn. } 36.
\]

\( \square \)
The next lemma shows that probability measures supported on a fine enough interval collection which induce the same distribution of interval membership have random minimum spanning trees with similar lengths. If \( \mu \) is supported on an interval collection \( \mathcal{I} \), let \( \mu^n_{\mathcal{I}} \) be the discrete random variable \( \phi_{\mathcal{I}}(x_1, \ldots, x_n) \).

**Lemma 43.** Let \( \epsilon > 0 \) and \( 0 < \alpha < d \). Let \( S_1 \supset S_2 \ldots \) be a nested sequence of interval collections with \( \|S_j\| \to 0 \), and let \( \mu \) be a probability measure supported on \( \cap_j S_j \) so that

\[
\left| n^{-\frac{d-\alpha}{d}} E^0_{\alpha}(x_1, \ldots, x_n) - c \right| < \epsilon/2
\]

with probability greater than \( 1 - \epsilon \) for an integer \( n > 0 \). Then there exists an \( M(\epsilon, n) \) so that if \( j > M(\epsilon, n) \) and \( \nu \) is any probability measure supported on \( S_j \) satisfying \( \nu^n_{S_j} = \mu^n_{S_j} \) (that is, \( \mu \) and \( \nu \) induce the same discrete probability distribution on the intervals in the set \( S_j \)) then

\[
\left| c - n^{-\frac{d-\alpha}{d}} E^0_{\alpha}(y_1, \ldots, y_n) \right| < \epsilon
\]

with probability greater than \( 1 - \epsilon \), where \( \{y_k\}_{k \in \mathbb{N}} \) are i.i.d. points sampled from \( \nu \).

**Proof.** For convenience, define

\[
F(x_1, \ldots, x_n) = \left| c - n^{-\frac{d-\alpha}{d}} E^0_{\alpha}(x_1, \ldots, x_n) \right|.
\]

Let \( \delta > 0 \) be as given in by the previous lemma for \( \epsilon_0 = n^{\frac{d-\alpha}{d}} \epsilon/2 \). Choose \( M(\epsilon, n) \) sufficiently large so that \( \|S_j\| < \delta \) for \( j > M(\epsilon, n) \).

Let \( j > M(\epsilon, n) \) and define

\[
V = \phi_{S_j} \left( F^{-1}(\epsilon/2) \right).
\]

That is, \( (l_1, \ldots, l_n) \in V \) if there exist points \( x_1 \in I_{l_1}, \ldots, x_n \in I_{l_n} \) so that \( F(x_1, \ldots, x_n) < \epsilon/2 \) (where \( S_j = \{I_k\} \)). By Equation 37

\[
\mu^n_{S_j}(V) > 1 - \epsilon
\]

and, because the discrete random variables \( \mu^n_{S_j} \) and \( \nu^n_{S_j} \) coincide by hypothesis,

\[
\nu^n_{S_j} > 1 - \epsilon.
\]

Therefore, with probability greater than \( 1 - \epsilon \), \( \phi_{\mathcal{I}}(y_1, \ldots, y_n) \in V \) so there exist \( z_1, \ldots, z_n \) satisfying \( F(z_1, \ldots, z_n) < \epsilon/2 \) and \( \phi_{\mathcal{I}}(y_1, \ldots, y_n) = \phi_{\mathcal{I}}(z_1, \ldots, z_n) \).
The third lemma compares the behavior of random minimum spanning trees on an interval collection with that of one on another interval collection formed by translating its intervals. A natural map between two interval collections $I$ and $J$ is an order-preserving homeomorphism $f : I \rightarrow J$ so that, for any $I \in I$, $f \mid I$ is a translation and $f(I)$ is an interval in $J$. Note that if $I$ and $J$ are sets of disjoint, congruent intervals so that $|I| = |J|$ and $\parallel I \parallel = \parallel J \parallel$, then there is a unique natural map between them.

**Lemma 44.** Let $I$ and $J$ be interval collections contained in $[0, 1]$, and suppose that there is a natural map $f : I \rightarrow J$. Let $0 < \alpha < d$, and let $\mu$ be a probability measure supported on $I$ so that

$$n^{-\frac{d-\alpha}{d}} E_\alpha^0 (x_n) \rightarrow c$$

in probability as $n \to \infty$, for some real number $c$. Then

$$n^{-\frac{d-\alpha}{d}} E_\alpha^0 (f(x_1), \ldots, f(x_n)) \rightarrow c$$

in probability as $n \to \infty$.

**Proof.** First, note that if $\{y_1, \ldots, y_n\}$ is an ordered set of points in $\mathbb{R}$, the edges of the minimum spanning tree $T(y_1, \ldots, y_n)$ are the intervals $[y_1, y_2], \ldots, [y_{n-1}, y_n]$. For a finite point set $x \subset I$ let $T_0(x)$ be the set of edges of $T(x)$ that are contained in an interval of $I$:
\[ T_0(x) = \{ e \in T(x) : e \subseteq I \text{ for some } I \in \mathcal{I} \} \]

and let \( T_1(x) \) consist of the remaining edges:

\[ T_1(x) = T(x) \setminus T_0(x) \]

See Figure 8. Let \( k = |\mathcal{I}| \) and note that \( |T_1(x)| < k \).

Recall that \( x_n \) is shorthand for \( \{x_1, \ldots, x_n\} \). If the edge \([x_j, x_{j+1}]\) is contained in \( T_0(x_n) \), then \([x_j, x_{j+1}] \subseteq I \) for some \( I \in \mathcal{I} \), and by the definition of a natural map there is a \( J \in \mathcal{J} \) so that \( f(I) = J \) and \( f|_I \) is a translation. Therefore \([f(x_j), f(x_{j+1})]\) is an interval in \( T_0(f(x_n)) \) of the same length as \([x_j, x_{j+1}]\). It follows that there is a length-preserving bijection between the edges of \( T_0(x_n) \) and \( T_0(f(x_n)) \), and

\[
\sum_{e \in T_0(x_n)} |e|^{\alpha} = \sum_{e \in T_0(f(x_n))} |e|^\alpha.
\]

For \( \epsilon > 0 \), choose \( N \) sufficiently large so that for all \( n > N \)

\[
k n^{-\frac{d-\alpha}{\alpha}} < \epsilon/4
\]

and

\[
|n^{-\frac{d-\alpha}{\alpha}} E_0^\alpha(x_n) - c| < \epsilon/2
\]

with probability greater than \( 1 - \epsilon \).

Let \( n > N \). We have that

\[
\left| E_0^\alpha(f(x_n)) - E_0^\alpha(x_n) \right| \leq \left| \sum_{e \in T_0(f(x_n))} |e|^\alpha - \sum_{e \in T_0(x_n)} |e|^\alpha \right| + \sum_{e \in T_1(f(x_n))} |e|^\alpha + \sum_{e \in T_1(x_n)} |e|^\alpha
\]

\[ = 0 + \sum_{e \in T_1(f(x_n))} |e|^\alpha + \sum_{e \in T_1(x_n)} |e|^\alpha \quad \text{using Equation 38}
\]

\[ < 2k \quad \text{all edges are contained in } [0,1]
\]

\[ < \epsilon/2n^{-\frac{d-\alpha}{\alpha}} \quad \text{using Equation 39}.
\]
Therefore,

\[
\left| n^{-\frac{d_{\alpha}}{d}} E^0_\alpha (f(x_n)) - c \right| \leq n^{-\frac{d_{\alpha}}{d}} \left| E^0_\alpha (f(x_n)) - E^0_\alpha (x_n) \right| + n^{-\frac{d_{\alpha}}{d}} E^0_\alpha (x_n) - c \right| < \frac{\epsilon}{2} + \frac{\epsilon}{2} \\
= \epsilon
\]

with probability greater than \(1 - \epsilon\), where we used the previous computation and Equation 40. \(\square\)

We are now ready to construct the counterexample.

As described in the introduction, our counterexample is related to the Cantor set. The Cantor set can be defined in terms of a middle thirds operation on interval collections. If \(I\) is an interval, let \(K(I)\) be the set of two intervals of length \(1/3|I|\)

\[K(I) = \left\{ \frac{1}{3}I, \frac{1}{3}I + \frac{2}{3}|I| \right\},\]

and if \(\mathcal{I}\) is an interval collection let

\[K(\mathcal{I}) = \{ K(I) : I \in \mathcal{I} \}.\]

Define \(T_m\) to be the set of intervals obtained by applying \(K\) to \(\{ [0,1] \} \) \(m - 1\) times. \(T_m\) consists of \(2^{m-1}\) intervals of length \((1/3)^{m-1}\). Then the Cantor set is

\[C = \cap_{m \in \mathbb{N}} T_m.\]

See Figure 9.

We define two more operations on interval collections. One produces slightly thinner intervals than \(K\) does, and the other produces slightly thicker intervals. If \(I\) is an interval, let

\[L(I) = \left\{ \left( \frac{5}{7} \right), \left( \frac{1}{3} \right) I, \left( \frac{5}{7} \right), \left( \frac{1}{3} \right) |I| + \left( 1 - \frac{5}{7} \right), \left( \frac{1}{3} \right) \right\} I \]
Figure 10. The interval operations $L$ and $\Gamma$ applied $T_2$, the second interval collection used in the definition of the Cantor set.

and

$$\Gamma(I) = \left\{ \left( \frac{7}{5} \right) \left( \frac{1}{3} \right) I, \left( \frac{7}{5} \right) \left( \frac{1}{3} \right) |I| + \left( 1 - \left( \frac{7}{5} \right) \left( \frac{1}{3} \right) \right) I \right\}.$$

If $\mathcal{I}$ is an interval collection, define $L(\mathcal{I})$ and $\Gamma(\mathcal{I})$ by performing the operation on each interval in the collection. See Figure 10. The scaling factor $\frac{7}{5}$ was chosen so that the intervals of $\Gamma(S_k)$ are disjoint.

If $S_1 \supset S_2 \supset S_3 \ldots$ is a nested sequence of interval collections, there is natural probability measure $\mu_S$ on $\bigcap_n S_n$ that assigns equal probability to each interval of $S_j$, for each value of $j$. That is,

$$\mu_S(I) = \frac{1}{|S_j|} \text{ for } I \in S_j.$$

For example, the natural measure on the Cantor set is $\mu_T$, where $T_1 \supset T_2 \supset T_3 \ldots$ is the nested sequence of interval collections defined above (and depicted in Figure 9). It assigns probability $1/2$ to each interval in $T_2$, probability $1/4$ to each interval in $T_3$, and so on.

Proof of Counterexample 4. Set $d = \frac{\log(2)}{\log(3)}$ and choose $0 < \alpha < d$. Also, let $\mu$ and $\nu$ be the natural probability measures on $C$ and $\frac{5}{7}C$, where $C$ is the Cantor set. Let $\{x_j\}_{j \in \mathbb{N}}$ and $\{y_j\}_{j \in \mathbb{N}}$ be i.i.d. samples from $\mu$ and $\nu$, respectively. Assume that there is a real number $c$ so that

$$n^{-\frac{d}{\pi} \alpha} E_0^0(x_1, \ldots, x_n) \to c$$

in probability as $n \to \infty$. If this was false, $C$ would be our desired example. Theorem 3 implies that $c > 0$. By rescaling the Cantor set, we have that

$$n^{-\frac{d}{\pi} \alpha} E_0^0(y_1, \ldots, y_n) \to \left( \frac{5}{7} \right) ^\alpha c$$

in probability as $n \to \infty$. 

We will construct a nested sequence of interval collections $S_1 \supset S_2 \supset S_3 \ldots$ mostly by applying the middle thirds operation $K$, but infrequently and alternately applying the operations $L$ and $\Gamma$.

Let $\{\epsilon_i\}$ be a sequence of real numbers converging to zero. We proceed by induction. Let $n_1$ be large enough so
\[
\left| c - n_1^{-\frac{d_\alpha}{x}} E_0^0 (x_1, \ldots, x_{n_1}) \right| < \epsilon_1/2
\]
with probability greater than $1 - \epsilon_1$, choose $m_1 > M(\epsilon_1, n_1)$, where $M(\epsilon_1, n_1)$ is as given in Lemma 43. Let $S_1 = T_{m_1}$, where $T_{m_1}$ is the $m_1$-th interval collection from the construction of the Cantor set. Then, by the definition of $M(\epsilon_1, n_1)$, if $\sigma$ is any probability measure $\sigma$ satisfying
\[
\sigma(I) = \frac{1}{|S_1|} \text{ for } I \in S_1
\]
(that is, $\sigma$ assigns the same probabilities to intervals in $S_1$ as $\mu$ does) then
\[
\left| c - n_1^{-\frac{d_\alpha}{x}} E_0^0 (x_1, \ldots, x_{n_1}) \right| < \epsilon_1
\]
with probability greater than $1 - \epsilon_1$. (Note that we are indexing the sets $S_j$ differently than described in the introduction but the resulting example is the same.)

By way of induction suppose that there are integers $n_1, \ldots, n_{k-1}$ and a nested sequence of interval collections $S_1 \supset \ldots \supset S_{k-1}$ so that

- For odd $i = 1, \ldots, k - 1$, $S_i$ consists of $2^{b_i}$ disjoint intervals of length $\left(\frac{1}{3}\right)^{b_i}$ for some integer $b_i$.

- For even $i = 2, \ldots, k - 1$, $S_i$ consists of $2^{b_i}$ disjoint intervals of length $\frac{5}{7} \left(\frac{1}{3}\right)^{b_i}$ for some integer $b_i$.

and, furthermore, if $\sigma$ is any probability measure on $S_{k-1}$ satisfying
\[
\sigma(I) = \frac{1}{|S_j|} \text{ for } I \in S_j, j = 1, \ldots, k - 1
\]
then if $\{z_j\}_{j \in \mathbb{N}}$ are i.i.d. samples from $\sigma$,

- for odd $i = 1, \ldots, k - 1$,
\[
\left| c - n_i^{-\frac{d_\alpha}{x}} E_0^0 (x_1, \ldots, x_{n_i}) \right| < \epsilon_i
\]
with probability greater than $1 - \epsilon_i$. 

• for even $i = 2, \ldots, k - 1$, 
\[
\left(\frac{5}{7}\right)^\alpha c - n_i^{-\frac{d-\alpha}{d}} E^0_\alpha (x_1, \ldots, x_{n_i}) < \epsilon_i
\]
with probability greater than $1 - \epsilon_i$.

If $k$ is odd, let $I_k = \Gamma (S_{k-1})$, so $I_k$ consists of $2^{b_k-1+1}$ disjoint intervals of length $(\frac{1}{3})^{b_k-1+1}$. It follows that there is a natural map $f_k : T_{b_k-1+1} \rightarrow I_k$, where $T_{b_k-1+1}$ is the $(b_k-1 + 1)$-st interval collection in the construction of the Cantor set. Let $\mu_k$ be the pushforward of $\mu$ by $f_k$ (recall that $\mu$ is the natural measure on the Cantor set) and let $\{w_j\}_{j \in \mathbb{N}}$ be i.i.d. samples from $\mu_k$. $f_k$ is a natural map, so Lemma 44 and Equation 41 imply that 
\[
n^{-\frac{d-\alpha}{d}} E^0_\alpha (w_1 \ldots w_n) \rightarrow c
\]
in probability as $n \rightarrow \infty$. It follows that there exists an $n_k$ so that 
\[
\left| n_k^{-\frac{d-\alpha}{d}} E^0_\alpha (w_1, \ldots, w_{n_k}) - c \right| < \epsilon_k/2,
\]
with probability greater than $1 - \epsilon_k$. $\mu_k$ is supported on intersection of the nested interval collections 
\[
I_k = f_k (T_{b_k-1+1}) \supset f_k (T_{b_k-1+2}) \supset f_k (T_{b_k-1+3}) \ldots
\]
and $\| f_k (T_{b_k-1+j}) \|$ $\rightarrow$ 0 as $j \rightarrow \infty$ so the hypotheses of Lemma 43 are met; choose $j > M (\epsilon_k, n_k)$, where $M (\epsilon_k, n_k)$ is as defined in that Lemma and set $S_k = f_k (T_{b_k-1+j})$. Then, by the definition of $M (\epsilon_k, n_k)$, if $\sigma$ is any probability measure so that 
\[
\sigma (I) = \frac{1}{|S_k|} \text{ for } I \in S_k
\]
(that is, $\sigma$ assigns the same probabilities to intervals in $S_k$ as $\mu_k$ does) then 
\[
\left| n_k^{-\frac{d-\alpha}{d}} E^0_\alpha (z_1, \ldots, z_{n_k}) - c \right| < \epsilon_k
\]
with probability greater than $1 - \epsilon_k$, as desired.

The argument for even $k$ is very similar, except we set $I_k = L (S_{k-1})$, the intervals of $I_k$ have length $\frac{5}{7} (\frac{1}{3})^{b_k-1+1}$, $f_k$ is a natural map from $\frac{5}{7} T_{b_k-1+1}$ to $I_k$, $\mu_k$ is the pushforward of $\nu$ by $f_k$, and $c$ is replaced by $\left(\frac{5}{7}\right)^\alpha c$ in Equations 42 and 43.

Let $\sigma$ be the natural probability measure on $S = \cap_j S_j$ (the one that assigns equal probability to the intervals of $S_j$ for all values of $j$), and let $\{z_j\}_{j \in \mathbb{N}}$ be i.i.d. samples from $\sigma$. By construction 
\[
n^{-\frac{d-\alpha}{d}} E^0_\alpha (z_1, \ldots, z_{n_{2k}}) \rightarrow c
\]
but
\[ n_{2k+1}^{\frac{-d-\alpha}{\alpha}} P_{\alpha}^0 (z_1, \ldots, z_{n_{2k+1}}) \to \left( \frac{5}{7} \right)^{\alpha} c \]
in probability as \( k \to \infty \).

To complete the proof, we will show that \( \sigma \) is \( d \)-Ahlfors regular. Let \( x \in S \). As a first case, let \( m \in \mathbb{N} \) and consider the ball of radius \( \frac{1}{3^m} \) centered at \( x \), an interval of length \( \frac{2}{3^m} \). \( S_{m+1} \) contains \( 2^m \) intervals whose lengths are either \( \frac{1}{3^m} \) or \( \frac{5}{7} \frac{1}{3^m} \). \( B_{3^{-m}}(x) \) contains at least 1 interval of \( S_{m+1} \) (the one that has \( x \) as an element) and intersects at most 4 such intervals. Therefore,
\[ \sigma (B_{3^{-m}}(x)) \geq \frac{1}{|S_m|} = 2^{-m} = (3^{-m})^d \]
and
\[ \sigma (B_{3^{-m}}(x)) \leq \frac{4}{|S_m|} = 4 (2^{-m}) = 4 (3^{-m})^d . \]

Let \( 0 < \delta < 1 \), \( \epsilon_0 = 3^{|\log_3(\delta)|} \), and \( \epsilon_1 = 3^{|\log_3(\delta)|} \), so
\[ \epsilon_0 \leq \delta < 3 \epsilon_0 \text{ and } \epsilon_1 / 3 < \delta \leq \epsilon_1 . \]

By our previous computations,
\[ \sigma (B_{\delta}(x)) \geq \sigma (B_{\epsilon_0}(x)) \geq \epsilon_0^d \geq 3^{-d} \delta^d \]
and
\[ \sigma (B_{\delta}(x)) \leq \sigma (B_{\epsilon_1}(x)) \leq 4 \epsilon_1^d \leq 4 (3^d \delta^d) . \]

Therefore, \( \sigma \) is \( d \)-Ahlfors regular with \( \delta_0 = 1 \) and \( c = 4 (3^d) \).

\[ \square \]

The construction for general \( d \in (0, 1) \) is nearly identical, but is based on the middle-\( \beta \) Cantor set rather than the middle thirds Cantor set. Let \( 0 < \beta < 1 \) and \( \gamma = \frac{1-\beta}{2} \).

For an interval \( I \) define
\[ K_\beta (I) = \{ \gamma I, \gamma I + (1 - \gamma) | I | \} , \]
so \( K_\beta (I) \) consists of two intervals of length \( \gamma | I | \) obtained by removing an interval of length \( \beta | I | \) from the middle of \( I \). Let \( T_1^\beta = [0, 1] \), and inductively define \( T_k^\beta = K \left( T_{k-1}^\beta \right) \). If \( T^\beta = \cap_k T_k^\beta \), then \( T \) is the union of two separated copies of itself rescaled by \( \gamma \), and the natural measure on \( T \) is Ahlfors regular of dimension
\[ d := \frac{\log (2)}{\log (1/\gamma)} = \frac{\log (2)}{\log (2) - \log (1 - \beta)} . \]
Note that $d$ ranges between 1 and 0 as $\beta$ ranges from 0 to 1. To finish the construction, repeat the previous argument verbatim except replace $\frac{7}{5}$ with a scaling factor $\eta$ so that

$$1 - \beta < \eta < 1$$

and $\frac{7}{5}$ with $\frac{1}{\eta}$. This will produce a $d$-Ahlfors regular measure so that if $0 < \alpha < d$ then $n^{-\frac{d-\alpha}{d}} E_\alpha(x_1, \ldots, x_n)$ oscillates between a positive constant and $\eta^\alpha$ times that constant.

**Appendix B. Scaling of Persistent Homology**

We provide computational evidence that the hypotheses of Theorem 8 hold in many cases. We examine four examples in $\mathbb{R}^3$ — the natural measures on the Menger sponge and the Sierpiński triangle cross an interval, the uniform measure on two tori stacked one above the other, and empirical data from earthquake hypocenters. See Figure 11. The first three are Ahlfors regular measures, with dimensions of $\frac{\log(20)}{\log(3)} \approx 2.727$, $1 + \frac{\log(3)}{\log(2)} \approx 2.585$, and 2, respectively. Note that $\gamma_2^i \leq 2.5$ [60], so the first two examples are known to meet all requirements of Theorem 8 for $i = 1$ except for perhaps the scaling of the expectation and variance of the number of intervals.

We sample points from the natural measures on the Menger sponge and the Sierpiński triangle using the procedures described in [42]. The rejection sampling algorithm developed in [26] was used to sample points from the uniform distribution of the torus $\left(\sqrt{x^2 + y^2} - R\right)^2 + z^2 = r^2$ with $R = 2$ and $r = 1$. The $z$-coordinate was
The earthquake hypocenter data comes from the Hauksson–Shearer Waveform Relocated Southern California earthquake catalog [37, 46, 58]; data was processed as in [42]. Persistent homology was computed using the implementation of the Alpha complex in GUDHI [52, 57].

Figure 12 shows the empirical expectation of $|PH_i(x_1, \ldots, x_n)|/n$ for each of the four examples, and $i = 1, 2$. In each case, the quantity appears to limit to a constant with $n$, indicating linear scaling of the number of intervals. Figure 13 shows the empirical variance of $|PH_i(x_1, \ldots, x_n)|$ divided by $n^2$ for three examples, and $i = 1, 2$. translated by 3 with probability $\frac{1}{2}$. The earthquake hypocenter data comes from the Hauksson–Shearer Waveform Relocated Southern California earthquake catalog [37, 46, 58]; data was processed as in [42]. Persistent homology was computed using the implementation of the Alpha complex in GUDHI [52, 57].
divided by $n^2$ for the three regular examples. This quantity decreases toward zero for all examples.
